A Sightseeing Tour of mm Interferometry

Jérôme PETY (Obs. de Paris/IRAM)

4th IRAM Millimeter Interferometry School Nov. 22 - Nov. 26 2004, Grenoble

Towards Higher Resolution: I. Problem

Telescope resolution:

- $\sim \lambda/D$;
- IRAM-30m: $\sim 11''$ @ 1 mm.

Needs to:

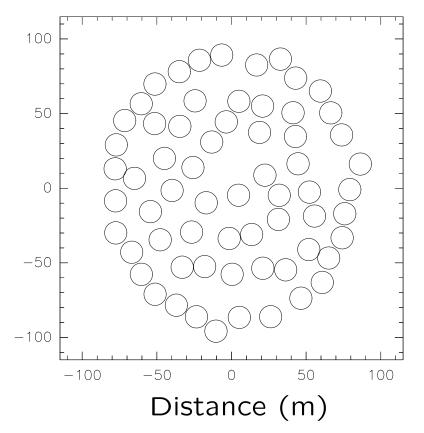

- increase *D*;
- increase precision of telescope positionning;
- keep high surface accuracy.
- ⇒ Technically difficult (perhaps impossible?).

Towards Higher Resolution: II. Solution

Aperture Synthesis: Replacing a single large telescope by a collection of small telescope "filling" the large one.

⇒ Technically difficult but feasible.

ALMA

Vocabulary and notations:

Baseline Line segment between two antenna.

 b_{ij} Baseline length between antenna i and j.

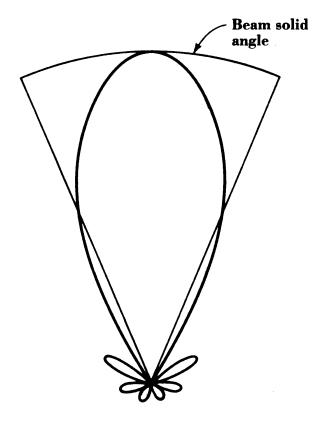

Configuration Antenna layout (e.g. compact configuration).

D configuration size (e.g. 150 m).

Primary beam resolution of one antenna (e.g. 27" @ 1 mm).

Synthesized beam resolution of the array (e.g. 2'' @ 1 mm).

Parenthesis: PSF = Diffraction Pattern = Beam Pattern

Single-Dish sensitivity in polar coordinates.

Combination of:

- Antenna properties;
- Optical system (i.e. how the waves are feeding the receiver).

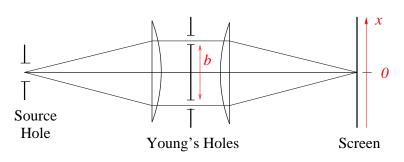

Typical kind:

Optic/IR Airy function; Radio Gaussian function.

(Lecture by P. Hily-Blant)

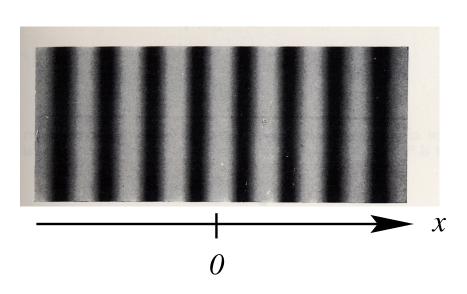

Young's Experiment

Setup

Lens ⇒ Fraunhofer conditions (i.e. Plane waves as if the source were placed at infinity).

Obtained image of interference: fringes

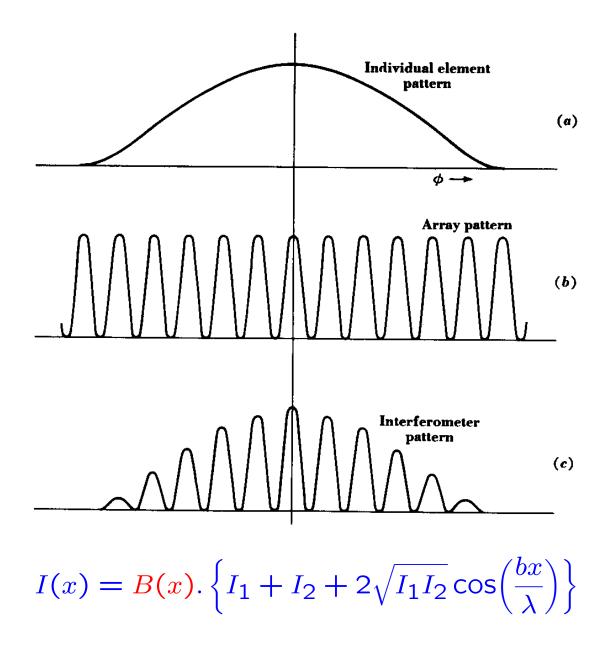

$$I(x) = I_1 + I_2 + 2\sqrt{I_1 I_2} \cos\left(\frac{bx}{\lambda}\right)$$

 $\begin{cases} \lambda \text{ Source wavelength;} \\ b \text{ Distance between the} \\ \text{two Young's holes;} \end{cases}$

 $oldsymbol{x}$ Distance from the optical center on the screen.

Effect of the Antenna Diffraction Pattern

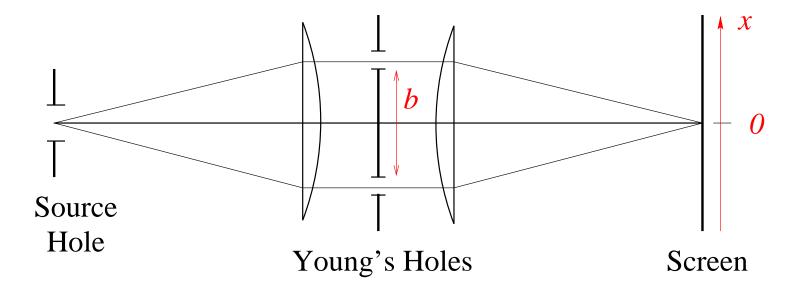

Effect of the Source Hole Size: I. Description

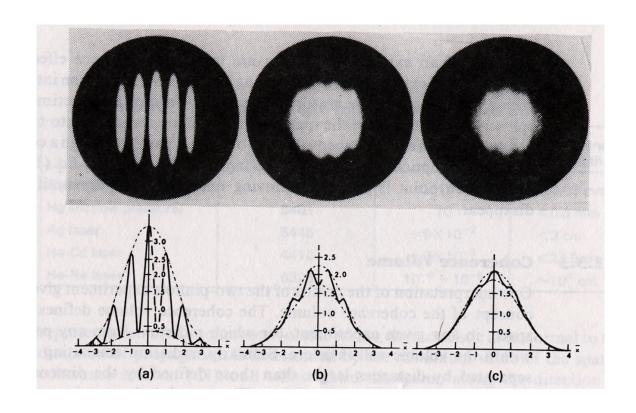

Hypothesis: Monochromatic source (but not a laser).

Description:

- The Source Hole Size is increased.
- Everything else is kept equal.

Effect of the Source Hole Size: II. Results

Fringes disappear! \Rightarrow {Fringe contrast is linked to the spatial properties of the source.

$$I(x) = I_1 + I_2 + 2\sqrt{I_1I_2}|C|\cos\left(\frac{bx}{\lambda} + \phi_C\right) \text{ with } |C| = \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}}$$

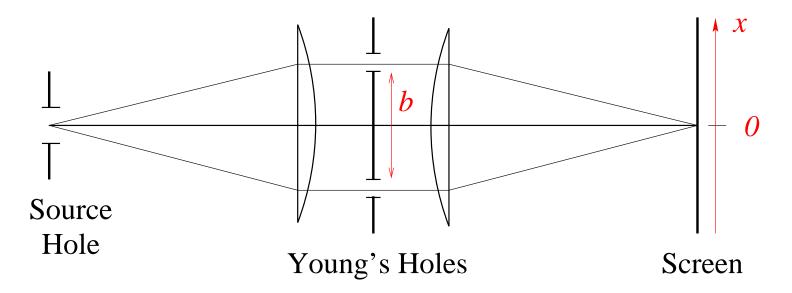

Effect of the Distance Between Young's Holes: I. Description

Hypothesis:

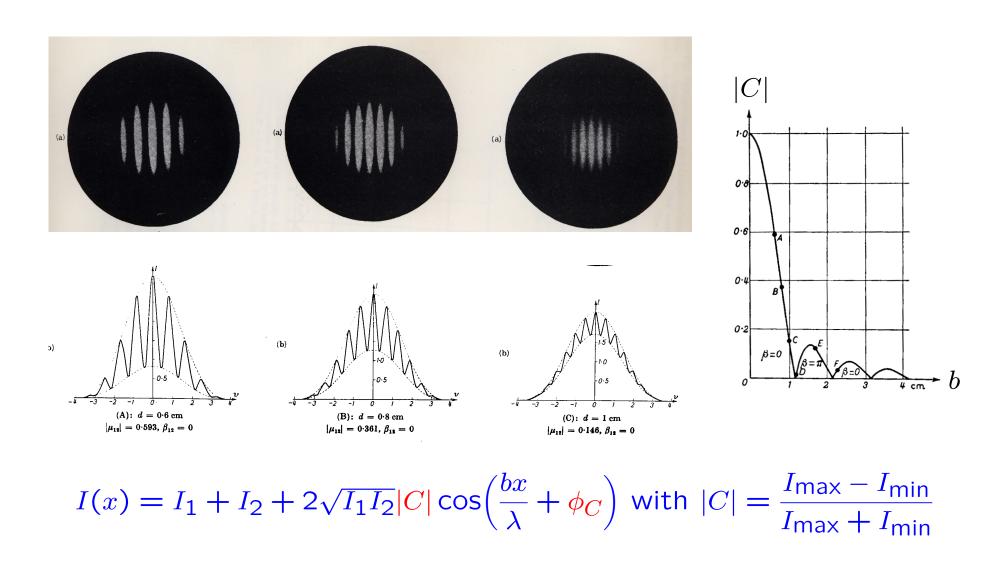

- Monochromatic source (but not a laser).
- The source hole is a circular disk.

Description:

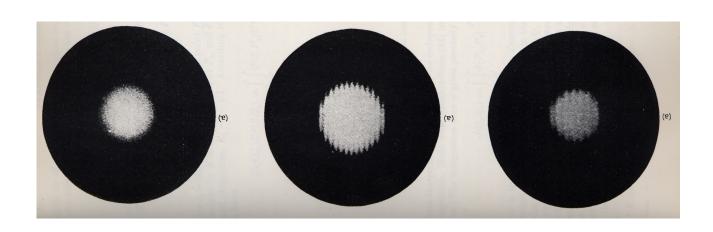

- The distance between the two Young's holes is increased.
- Everything else is kept equal (in particular the hole size).

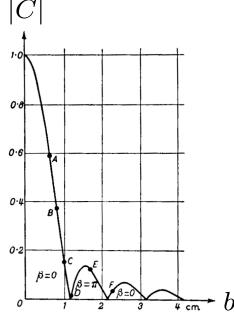

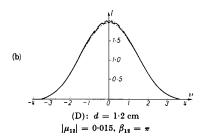

Effect of the Distance Between Young's Holes: II. Results

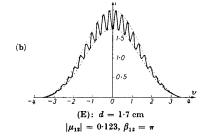

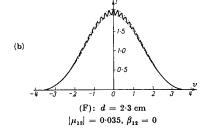

Effect of the Distance Between Young's Holes: II. Results (Continued)

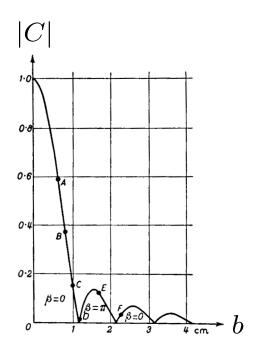

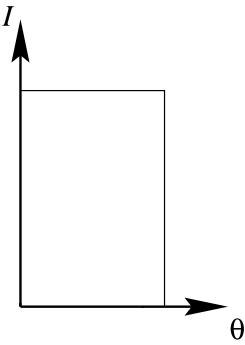

$$I(x) = I_1 + I_2 + 2\sqrt{I_1I_2}|C|\cos\left(\frac{bx}{\lambda} + \phi_C\right) \text{ with } |C| = \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}}$$

Measured Curve = 2D Fourier Transform of the Source

$$\frac{J_1(b)}{b} \stackrel{\mathsf{2D}}{\rightleftharpoons} \mathsf{FT} \mathsf{Heaviside}(\theta)$$

Source = Uniformly illuminated disk.

Theoretical Basis of the Aperture Synthesis

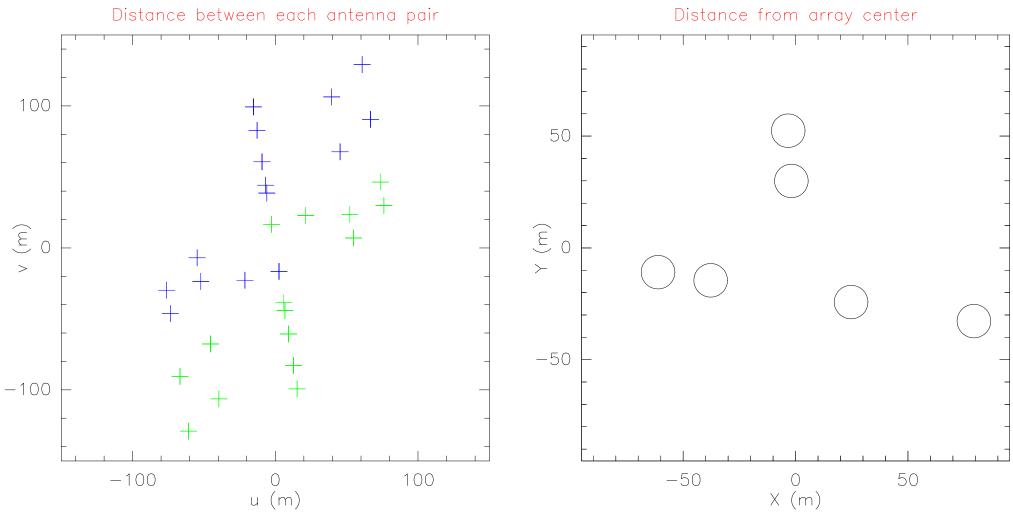

The van Citter-Zernike theorem
$$V_{ij}(b_{ij}) = C_{ij}(b_{ij}).I_{\mathsf{tot}} \overset{\mathsf{2D}}{\rightleftharpoons} F^{\mathsf{T}} B_{\mathsf{primary}}.I_{\mathsf{source}}$$

- Young's holes = Telescopes;
- Signal received by telescopes are combined by pairs;
- Fringe visibilities are measured.
- \Rightarrow One Fourier component of the source (*i.e.* one visibility) is measured by baseline (or antenna pair).
 - ⇒ Convention: Spatial frequencies are measured in meter.
 - \Rightarrow Each baseline length $b_{ij} =$ a spatial frequency.

An Example: the PdBI

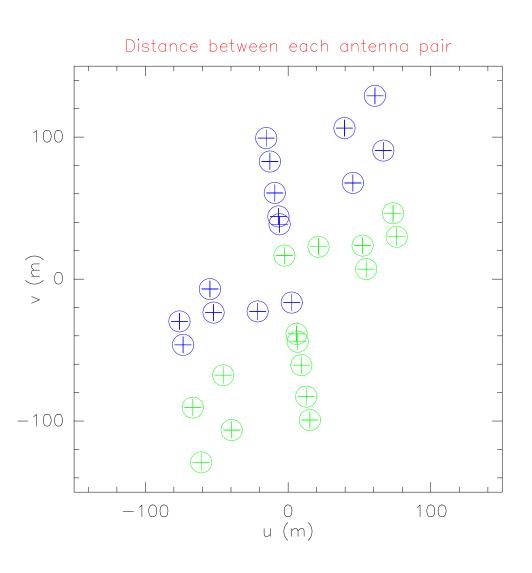

Number of baselines: N(N-1) = 30 for N = 6 antennas.

Convention: Fourier plane = uv plane.

Incomplete uv plane coverage \Rightarrow difficult to make a reliable image (Lectures by J. Pety and F. Gueth).

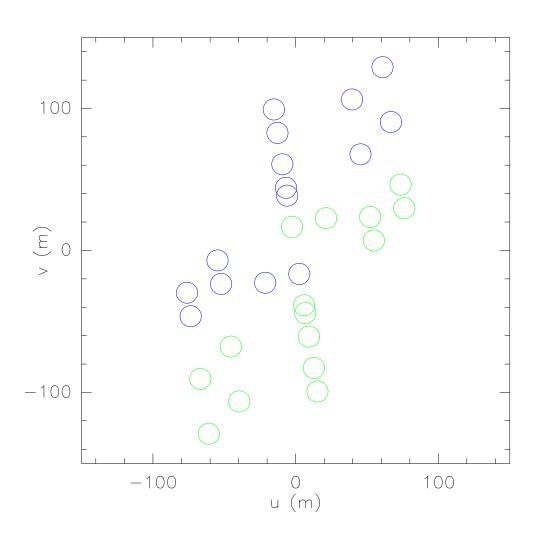

Each Visibility is a Weighted Sum of the Fourier Components of the Source

$$V_{ij}(b_{ij}) \stackrel{\text{2D FT}}{\rightleftharpoons} B_{\text{primary}}.I_{\text{source}}$$
 $i.e.\ V_{ij}(b_{ij}) = \left\{ \tilde{B}_{\text{primary}} * \tilde{I}_{\text{source}} \right\} (b_{ij})$
with $\tilde{B}_{\text{primary}}$ a Gaussian of FWHM=15 m.

 $\Rightarrow \begin{cases} \text{Indirect information on the source} \\ \text{(important for mosaicing)}. \end{cases}$

Precision: Spatial frequencies = baseline lengths projected in a plane perpendicular to the source mean direction.

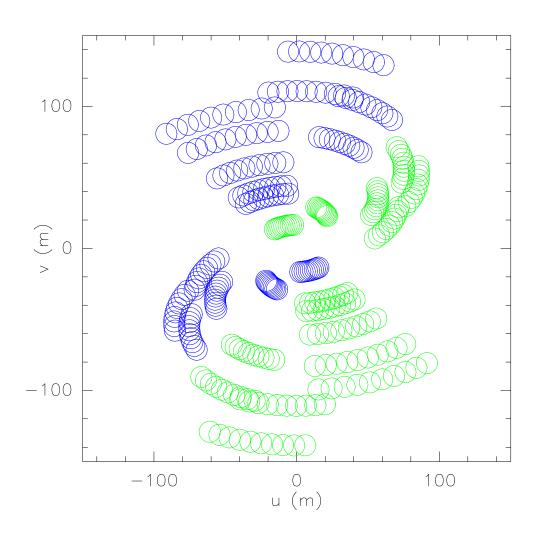

Advantage: As the earth rotates, the source sees different baseline lengths.

Precision: Spatial frequencies = baseline lengths projected in a plane perpendicular to the source mean direction.

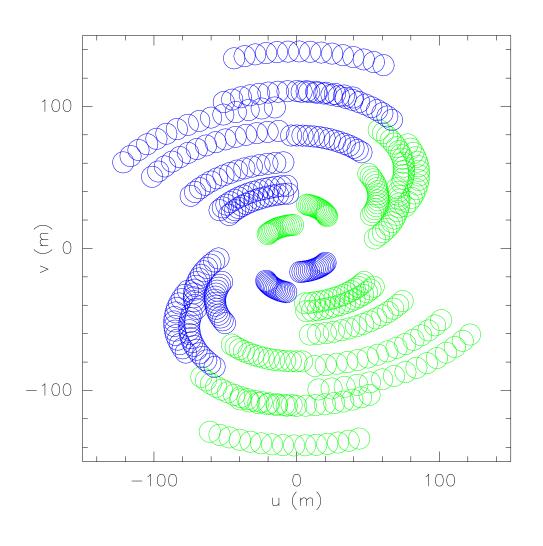

Advantage: As the earth rotates, the source sees different baseline lengths.

Precision: Spatial frequencies = baseline lengths projected in a plane perpendicular to the source mean direction.

Precision: Spatial frequencies = baseline lengths projected in a plane perpendicular to the source mean direction.

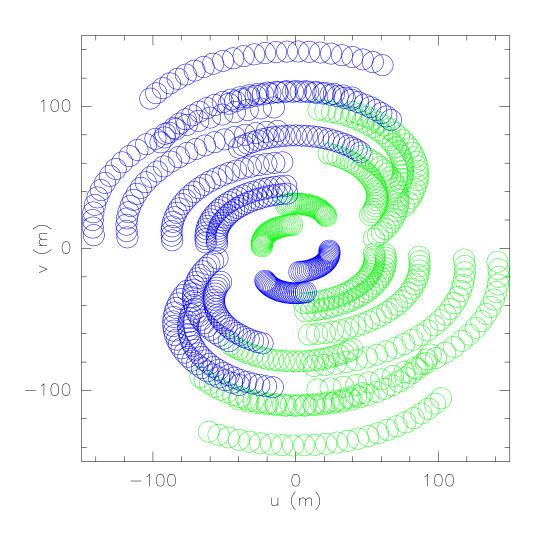

Advantage: As the earth rotates, the source sees different baseline lengths.

Precision: Spatial frequencies = baseline lengths projected in a plane perpendicular to the source mean direction.

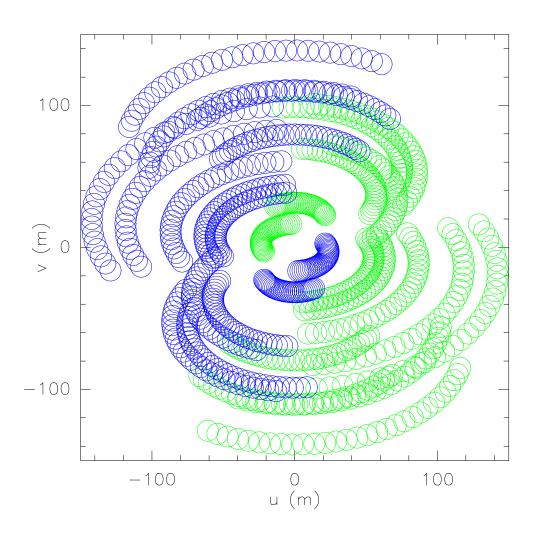

Advantage: As the earth rotates, the source sees different baseline lengths.

Delay Correction: I. Why?

Real life: Source not at zenith.

⇒ {Wave plane arrives at different moment on each antenna.

Temporal coherence:

- $E(t) = E_0 \cos(\omega t + \psi)$
- Temporally Incoherent Source
 = random phase changes.
- Coherence time: mean time over which wave phase = constant.

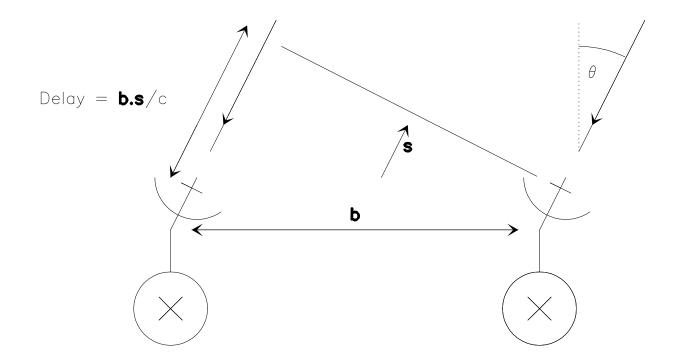

$$\psi = 0$$
 $\psi = 1.5$ $\psi = 0.5$

Problem: (Coherence time \leq delay) \Rightarrow fringes disappear!

Delay Correction: II. Earth rotation

Earth rotation:

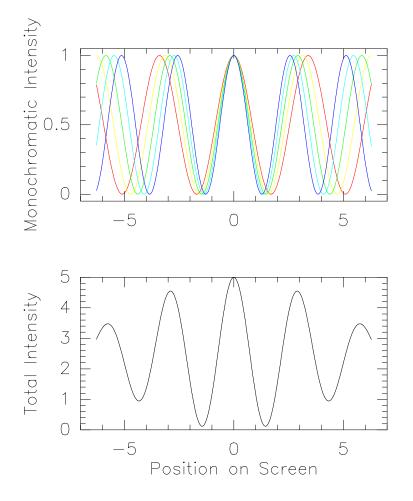

- Advantage: Super synthesis;
- Inconvenient: Delay correction varies with time!

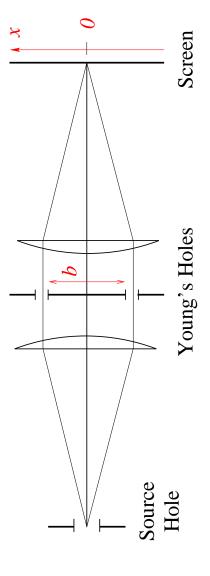

Real life: Observation of finite bandwidth.

⇒ polychromatic light.

Perfect delay correction ⇒ White fringes in 0.

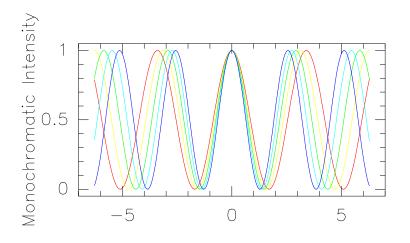

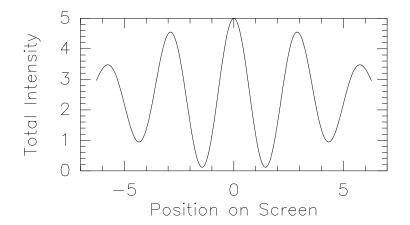

Real life: Observation of finite bandwidth.

⇒ polychromatic light.

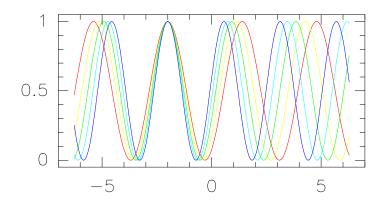

Perfect delay correction

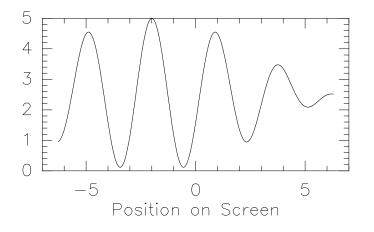

⇒ White fringes in 0.

- \Rightarrow Translation of the fringe pattern.
 - ⇒ Fringes seem to disappear.

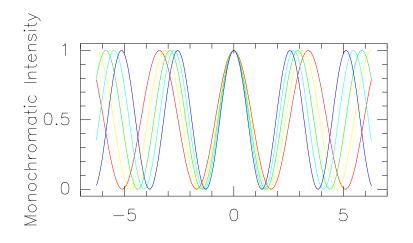

A Sightseeing Tour of mm Interferometry

Optic vs Radio Interferometer: I. Measurement Method

Detector {Kind Observable

Measure { Method Quantity

Interferometer kind

Optic

Quadratic

 $I = |EE^{\star}|$

Optical fringes

 $|C| = \frac{I_{\text{max}} - I_{\text{min}}}{I_{\text{max}} + I_{\text{min}}}$

Additive

Radio

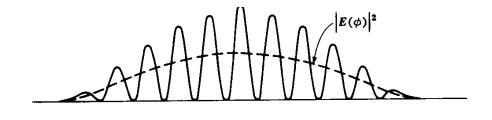

Linear (Heterodyne)

 $|E| \exp(i\psi)$

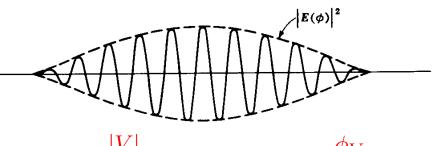

Electronic correlation

$$|V| \exp(i\phi_V) = \langle E_1.E_2 \rangle$$

Multiplicative

$$I_1 + I_2 + 2\sqrt{I_1 I_2} |C| \cos\left(\frac{bx}{\lambda} + \phi_C\right)$$

$$\underbrace{|V|}_{|E_1|\,|E_2|\,|C|}\cos\left(\frac{bx}{\lambda} + \overbrace{\phi_C}^{\phi_V}\right)$$

(Heterodyne: lecture by R. Lucas)

Optic vs Radio Interferometer: I. Measurement Method

Detector $\left\{ egin{array}{ll} \mbox{Kind} & \mbox{Quadratic} \ \mbox{Observable} & I = |EE^{\star}| \ \end{array} \right.$

Measure { Method Quantity

Interferometer kind

Optic

Quadratic

Optical fringes

 $|C| = \frac{I_{\text{max}} - I_{\text{min}}}{I_{\text{max}} + I_{\text{min}}}$

Additive

Radio

Linear (Heterodyne)

 $|E| \exp(i\psi)$

Electronic correlation

 $|V| \exp(i\phi_V) = \langle E_1.E_2 \rangle$

Multiplicative

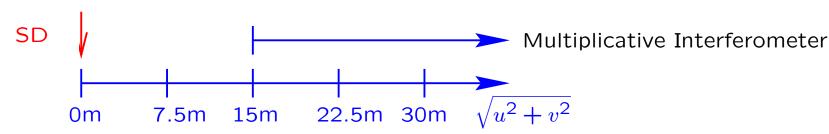

Multiplicative Interferometer

Avantage: all offsets are irrelevant ⇒ Much easier;

Inconvenient: Radio interferometer = bandpass instrument;

⇒ Low spatial frequencies are filtered out.

Optic vs Radio Interferometer: II. Atmospheric Influence

Atmosphere emits and absorbs: (Lecture #1 by J.-M. Winters). Signal = Transmission * Source + Atmosphere.

Good news: Atmospheric noise uncorrelated

⇒ Correlation suppresses it!

Bad news: Transmission depends on weather and frequency.

⇒ Astronomic sources needed to calibrate the flux scale! (Lectures by R. Lucas and F. Gueth)

Atmosphere is turbulent: \Rightarrow Phase noise (Lecture #2 by J.-M. Winters).

Timescale of atmospheric phase random changes:

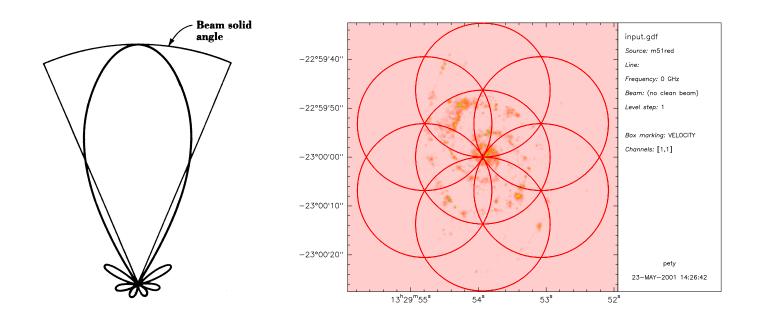

- Optic: 10-100 milli secondes;
- Radio: 10 minutes.
- ⇒ Radio permits phase calibration on a nearby point source (e.g. quasar).

Instantaneous Field of View

One pixel detector:

- Single Dish: one image pixel/telescope pointing;
- Interferometer: numerous image pixels/telescope pointing
 - Field of view = Primary beam size;
 - Image resolution = Synthesized beam size.

Wide-field imaging: \Rightarrow mosaicing (Lecture by F. Gueth).

Conclusion

mm interferometry:

- A bit more of theory;
- Lot's of experimental details (e.g. lecture by R. Lucas).

Why caring about technical details: Some of them must be understood to know whether you can trust your data.

By the end of this week, you should be ready to use PdBI! (Lecture by R. Neri and examples from users)
