

# Introduction to Millimeter Astronomy

Pierre Cox

IRAM Interferometry School 2008

# Millimeter waves probe cold matter

## ***VISIBLE***

### *Hot matter*

Stars between 3000 et 100,000 K  
Ionised gas: 10,000 K

## ***MILLIMETER***

### *Cold Matter*

Dust & Molecules  
3 à 70 K (-270 à -200 deg Celsius)

**STARS ARE BORN IN  
COLD MATTER**

Because molecular ISM is cold and opaque to the visible and UV, the sub/millimeter is key to probe molecular clouds through:

- Molecular rotational transitions, where the photon energy is  $\sim kT_k$
- Cold dust (10-20 K) emission
- Observations of high-z galaxies

### *Atmospheric windows: 3, 2, 1 and 0.8 mm*

The 3mm window (72-116 GHz) includes practically one rotation of *most* molecules.

Fortunate situation that the mm windows all include transition of CO, which is the most abundant molecule after H<sub>2</sub>

[J=1-0 at 115.271 GHz, J=2-1 at 230.538 GHz and J=3-2 at 345.796 GHz]

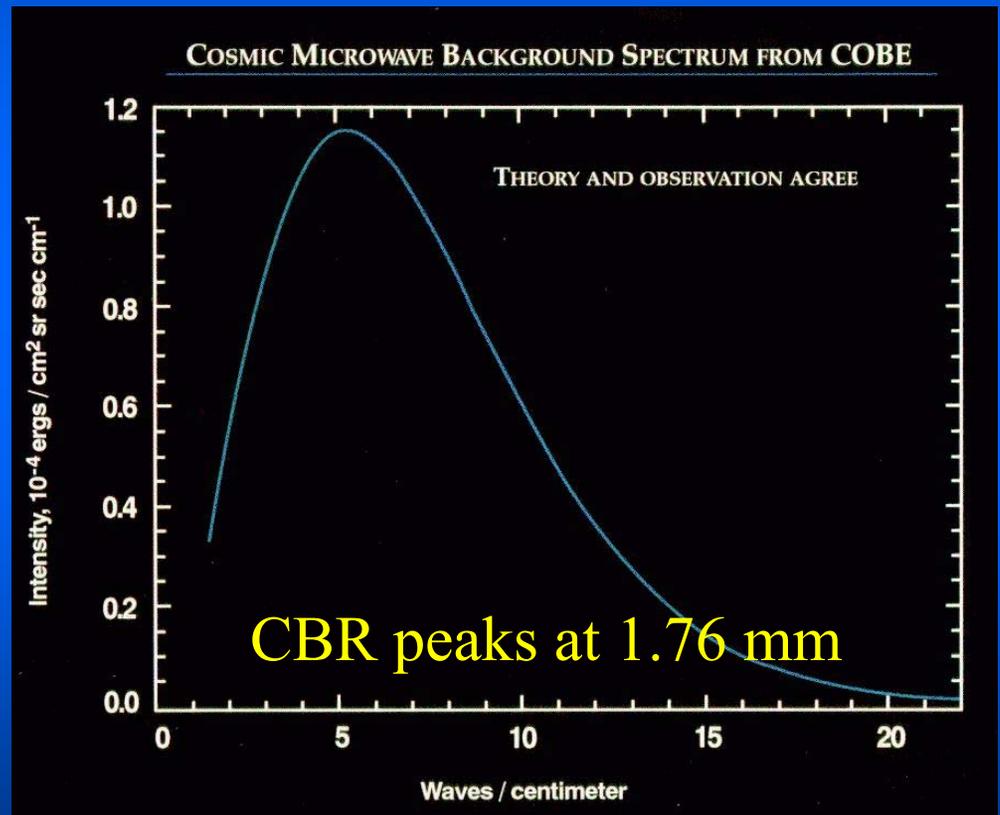

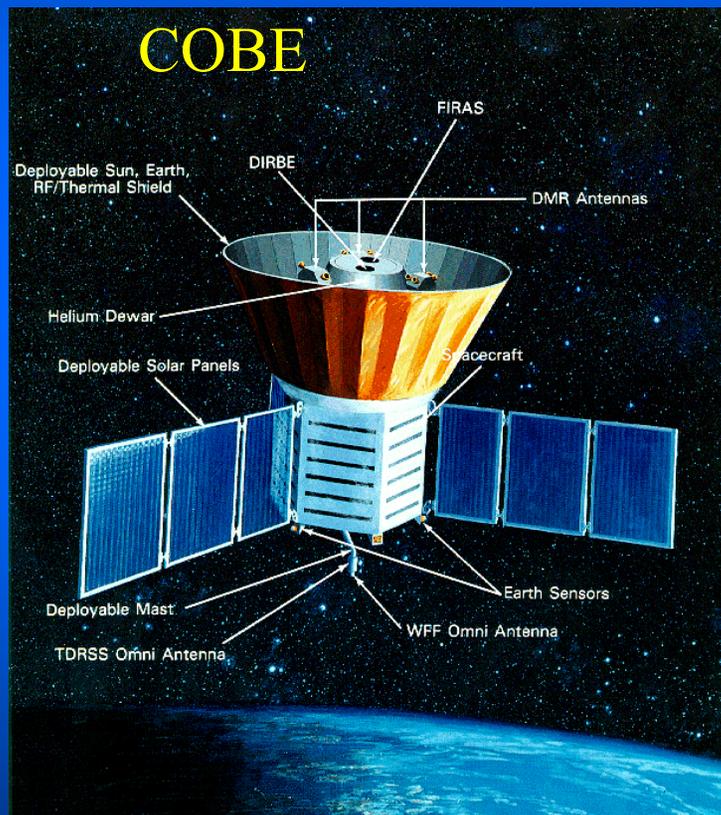

*Millimeter studies fully benefit from the advantages of radio astronomy for high velocity resolution with the heterodyne techniques, and the high angular resolution with large dishes or interferometers.*

# Interest of the mm/submm domain

$$h\nu = kT \quad \boxed{1.44 \text{ K} \equiv 30 \text{ GHz} \equiv 1 \text{ cm}^{-1}}$$

- Black-body emission peaks at  $\lambda_m = hc/3kT = 0.48/T \text{ cm}$
- Dust emission peaks at  $\lambda_m = hc/(3+\beta)kT = 0.3/T \text{ cm}$
- Typical energies involved in molecular transitions
- SED of galaxies
- SZ effect, interstellar scintillation (VLBI)
- Atmosphere transparency

# Black body emission: Cosmic Background Radiation

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

Diffuse Cloud

$$n=10-10^3 \text{ cm}^{-3}$$

$$T=20-100 \text{ K}$$

$$A_v < 1$$

Dark Cloud

$$n=10^3-10^6 \text{ cm}^{-3}$$

$$\underline{T=8-15 \text{ K}}$$

$$A_v > 1$$

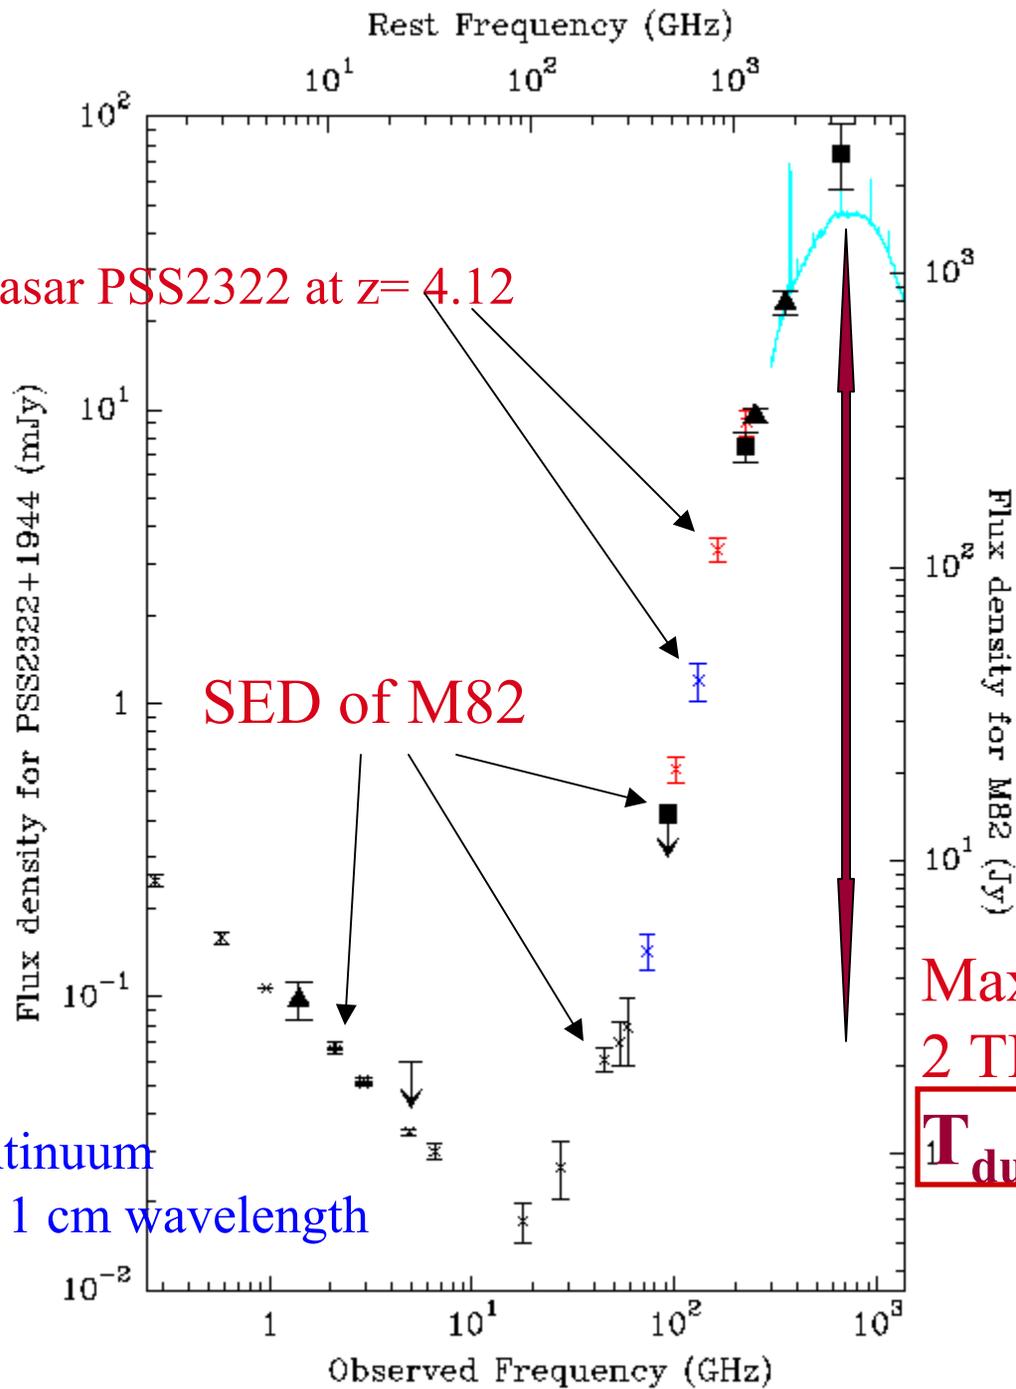

**Dust emission  
peaks at 0.3 mm**

SED of the quasar PSS2322 at  $z=4.12$

SED of M82

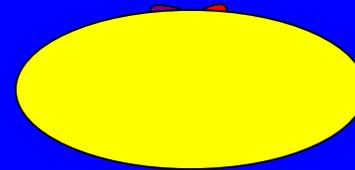

Minimum of continuum emission around 1 cm wavelength

Oct. 6-

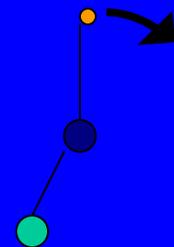

# Typical energies involved in molecular transitions

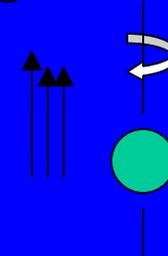

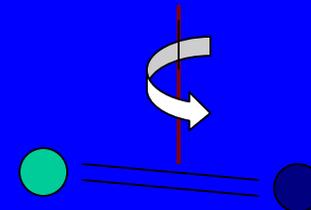

- Electronic transitions
- Vibrational transitions
- Rotational transitions
- Electronic/nuclear Spin interactions

stretching

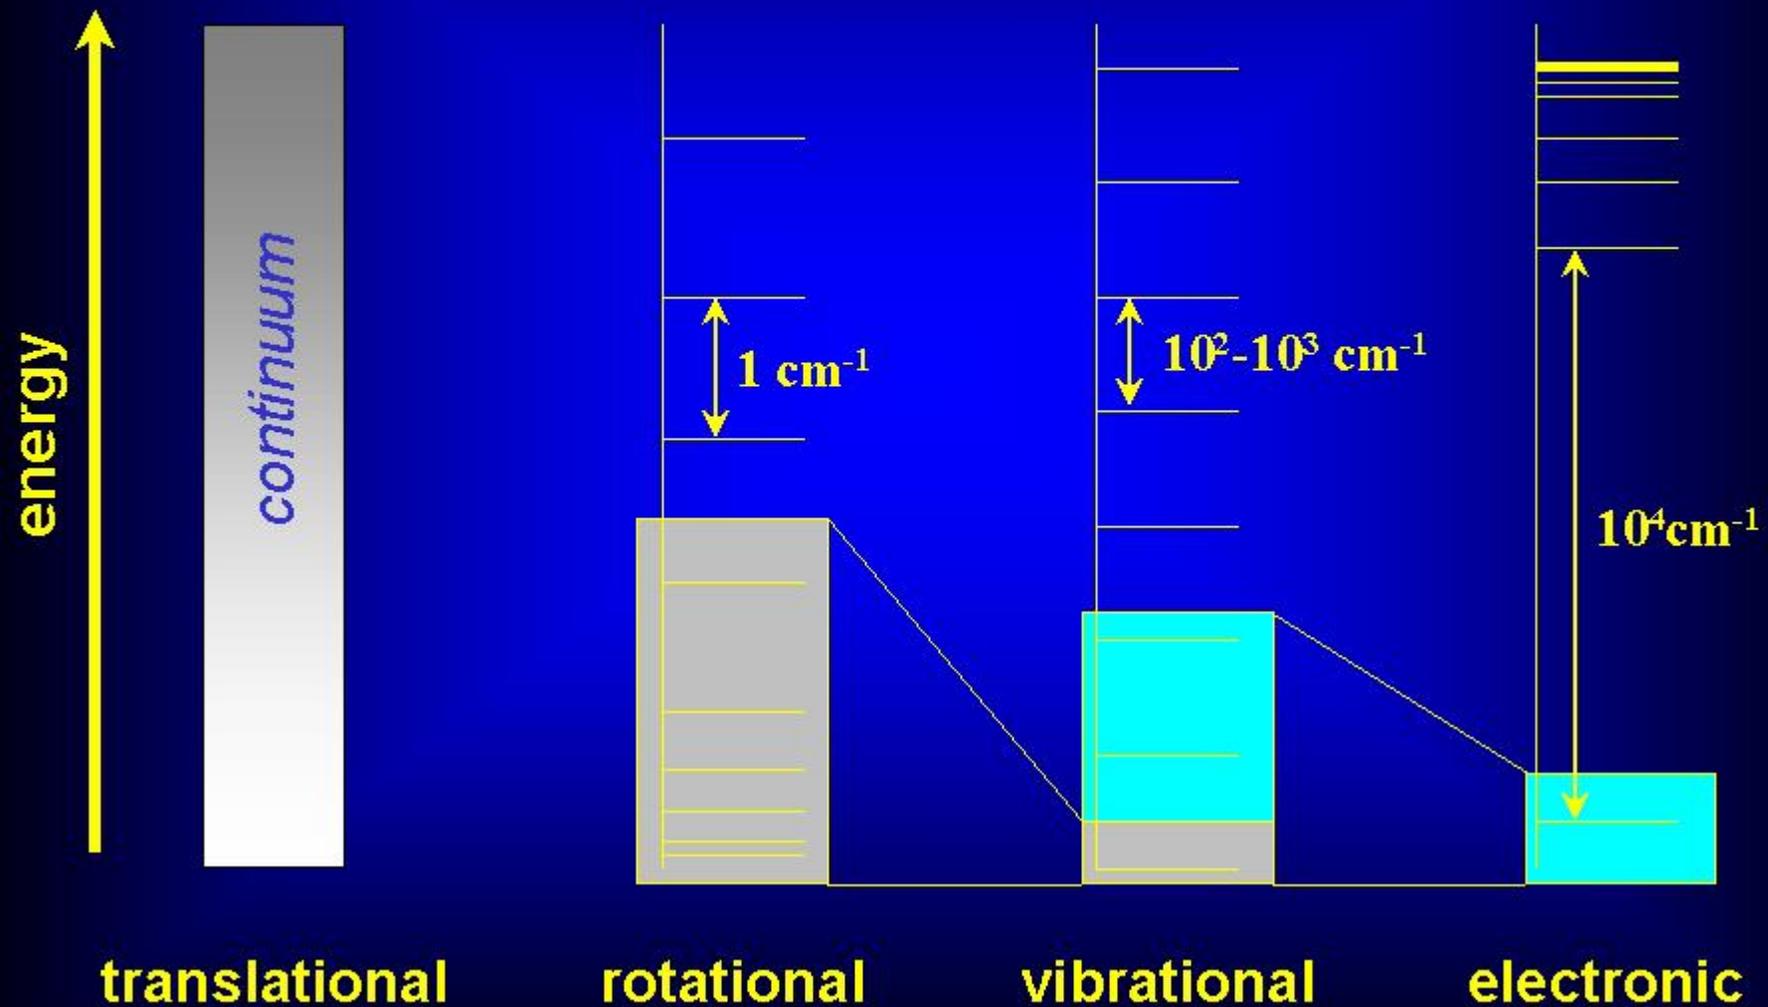

bending

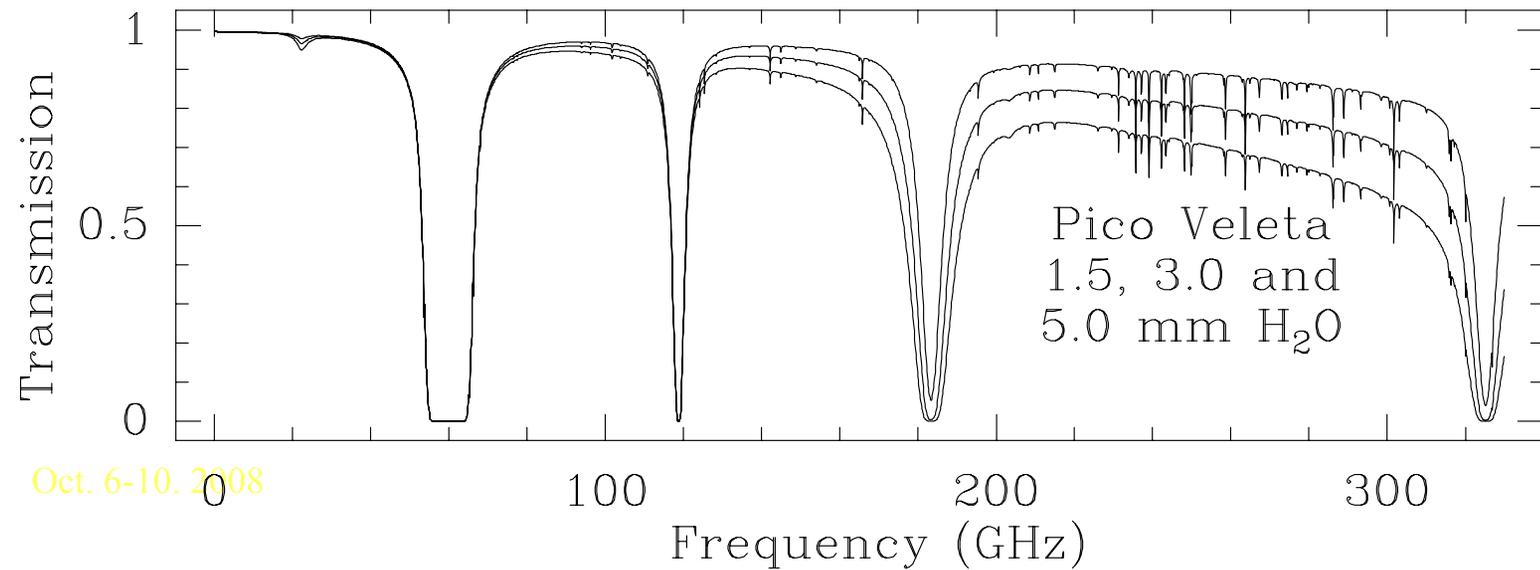

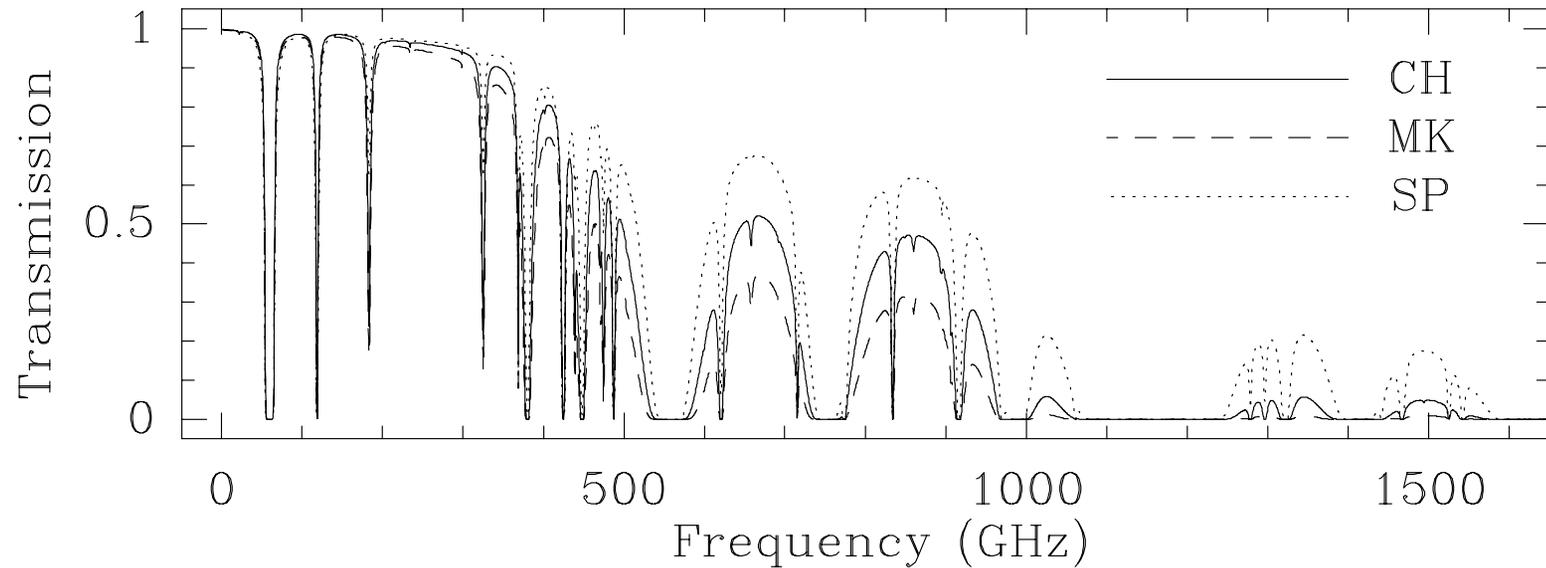

# energy level separations

low-energy rotational transitions of small molecules lie at mm wavelength

# Atmospheric transmission (calculations by J. Pardo)

Oct. 6-10, 2008

## Emission processes at sub/mm wavelengths

- Atoms: electronic (spin, Rydberg states)
- **Molecules**: electronic, vibrational, rotational
- Free electrons:
  - Synchrotron
  - Thermal free-free
- **Dust particles** (grey body radiation)

# Millimeter-wave Radio Telescopes

- Large collecting surface for sensitivity
- Large physical dimensions for angular resolution
- High altitude to reduce atmospheric water vapor absorption
- Heterodyne receivers for high spectral resolution ( $10^{-7}$  —  $10^{-8}$ )

IRAM 30-m telescope (Sierra Nevada, Spain)  
Alt. 2900 m; surface accuracy 50  $\mu\text{m}$  (night)

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

APEX 12-m telescope (Atacama, Chile)  
Altitude 5100 m; surface accuracy  $17\mu\text{m}$

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

# Sub/Millimeter Interferometers

Plateau de Bure 2500 m

6<sup>th</sup> IRAM Interferometry School 2008

# ALMA

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

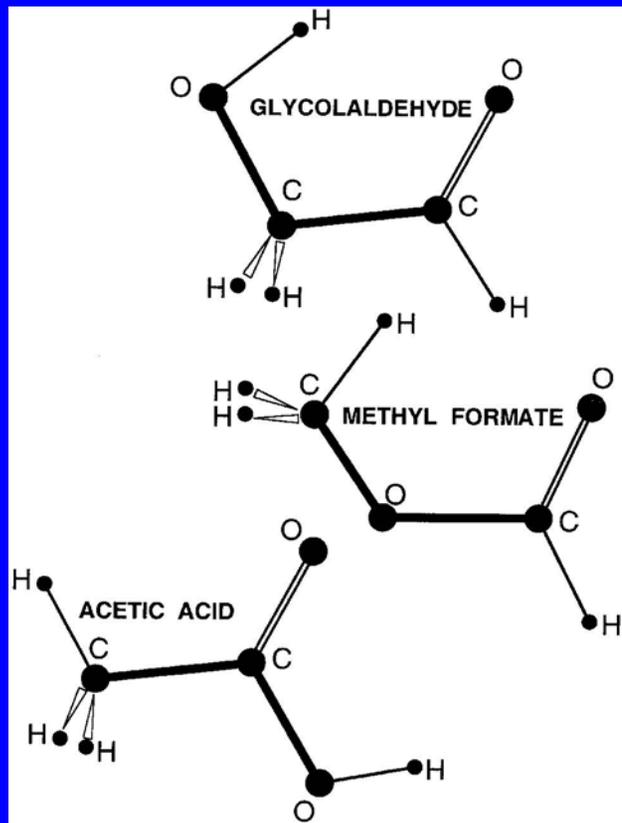

# Advantages of Interferometry

- ‡ **High angular resolution** (@  $\lambda=1$  mm: 0.25'' with PdB; 20  $\mu$ arcsec with VLBI)
- ‡ **Large collective area**
- ‡ **No need of reference position** (factor 2 in sensitivity replaced by  $N(N-1)/N^2$ )
- ‡ **Flatter baselines** (depends less on receiver/atmosphere stability).  
Makes possible composite spectra.
- ‡ **Field of view with many independent pixels** → good noise statistics makes possible secure detections down to 4 sigma.
- ‡ **Well suited for special observations:** polarimetry, SZ
- ‡ **Accurate source positions** (by stable atmosphere: HPBW/SNR)
- ‡ **Eliminates extended (foreground/background) emission**

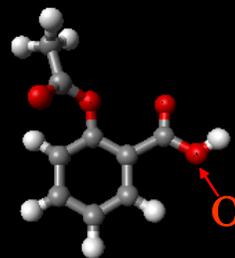

# Disadvantages of Interferometry

- **Several receivers to build**; more complex correlator, but heterodyne interferometry is easy
- **Short spacings filtered out**: extended source emission lost (partly recovered by mosaicing techniques)
- **Needs a stable atmosphere** (or needs phase corrections or self-calibration)
- Difficult to observe very strong sources, such as planets (unless modeled)

# Interstellar molecules

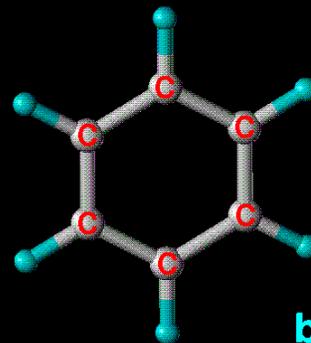

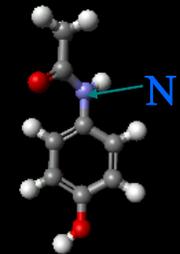

*Aspirine*

*Ibuprofeno*

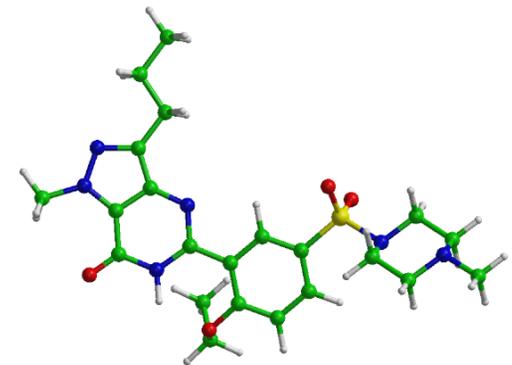

*Paracetamol  
or acetaminophen*

**benzene**

*Viagra*

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

## List of Interstellar Molecules (142, January 2006)

### Hydrogen Compounds

$H_2$	$HD$	$H_3^+$	$H_2D^+$		
-------	------	---------	----------	--	--

### Hydrogen and Carbon Compounds

<u><math>CH</math></u>	$CH^+$	$C_2$	$CH_2$	$C_2H$	$*C_3$
$CH_3$	$C_2H_2$	$C_3H$ (lin)	$c-C_3H$	$*CH_4$	$C_4$
$c-C_3H_2$	$H_2CCC$ (lin)	$C_4H$	$*C_5$	$*C_2H_4$	$C_5H$
$H_2C_4$ (lin)	$*HC_4H$	$CH_3C_2H$	$C_6H$	$*HC_6H$	$H_2C_6$
$*C_7H$	$CH_3C_4H$	$C_8H$	$*C_6H_6$		

### Hydrogen, Carbon (possibly) and Oxygen Compounds

<u><math>OH</math></u>	<u><math>CO</math></u>	$CO^+$	$H_2O$	$HCO$	$HCO^+$
$HOC^+$	$C_2O$	$CO_2$	$H_3O^+$	$HOCO^+$	$H_2CO$
$C_3O$	$CH_2CO$	$HCOOH$	$H_2COH^+$	$CH_3OH$	$CH_2CHO$
$CH_2CHOH$	$CH_2CHCHO$	$HC_2CHO$	$C_5O$	$CH_3CHO$	$c-C_2H_4O$
$CH_3OCHO$	$CH_2OHCHO$	$CH_3COOH$	$CH_3OCH_3$	$CH_3CH_2OH$	$CH_3CH_2CHO$
$(CH_3)_2CO$	$HOCH_2CH_2OH$	$C_2H_5OCH_3$	$(CH_2OH)_2CO$	$CH_3CONH_2$	

Molecular ions are in red. Free radicals are in purple. Closed-shell highly unstable molecules are in blue.

## Hydrogen, Carbon (possibly) and Nitrogen Compounds

<i>NH</i>	<i>CN</i>	$N_2$	<i>NH_2</i>	HCN	<b>HNC</b>
<b><math>N_2H^+</math></b>	NH <sub>3</sub>	<b>HCNH<sup>+</sup></b>	<b>H<sub>2</sub>CN</b>	<b>HCCN</b>	<b>C<sub>3</sub>N</b>

IRAM Interferometry School 2008

# Inter- & Circumstellar molecules

- 135 species (+-5 ?)
- 14 ions (and 2 anions)
- 29 free radicals (part of which identified in space prior to be studied in the laboratory)
- 19 isomers or highly unstable closed-shell molecules
- 18 molecules with refractory atoms, amidst which 8 silicon compounds
- 5 cycles, among which benzene (1 line!). No other benzenic ring detected, except perhaps PAHs.

# INTERSTELLAR & CIRCUMSTELLAR MOLECULES (May 2006)

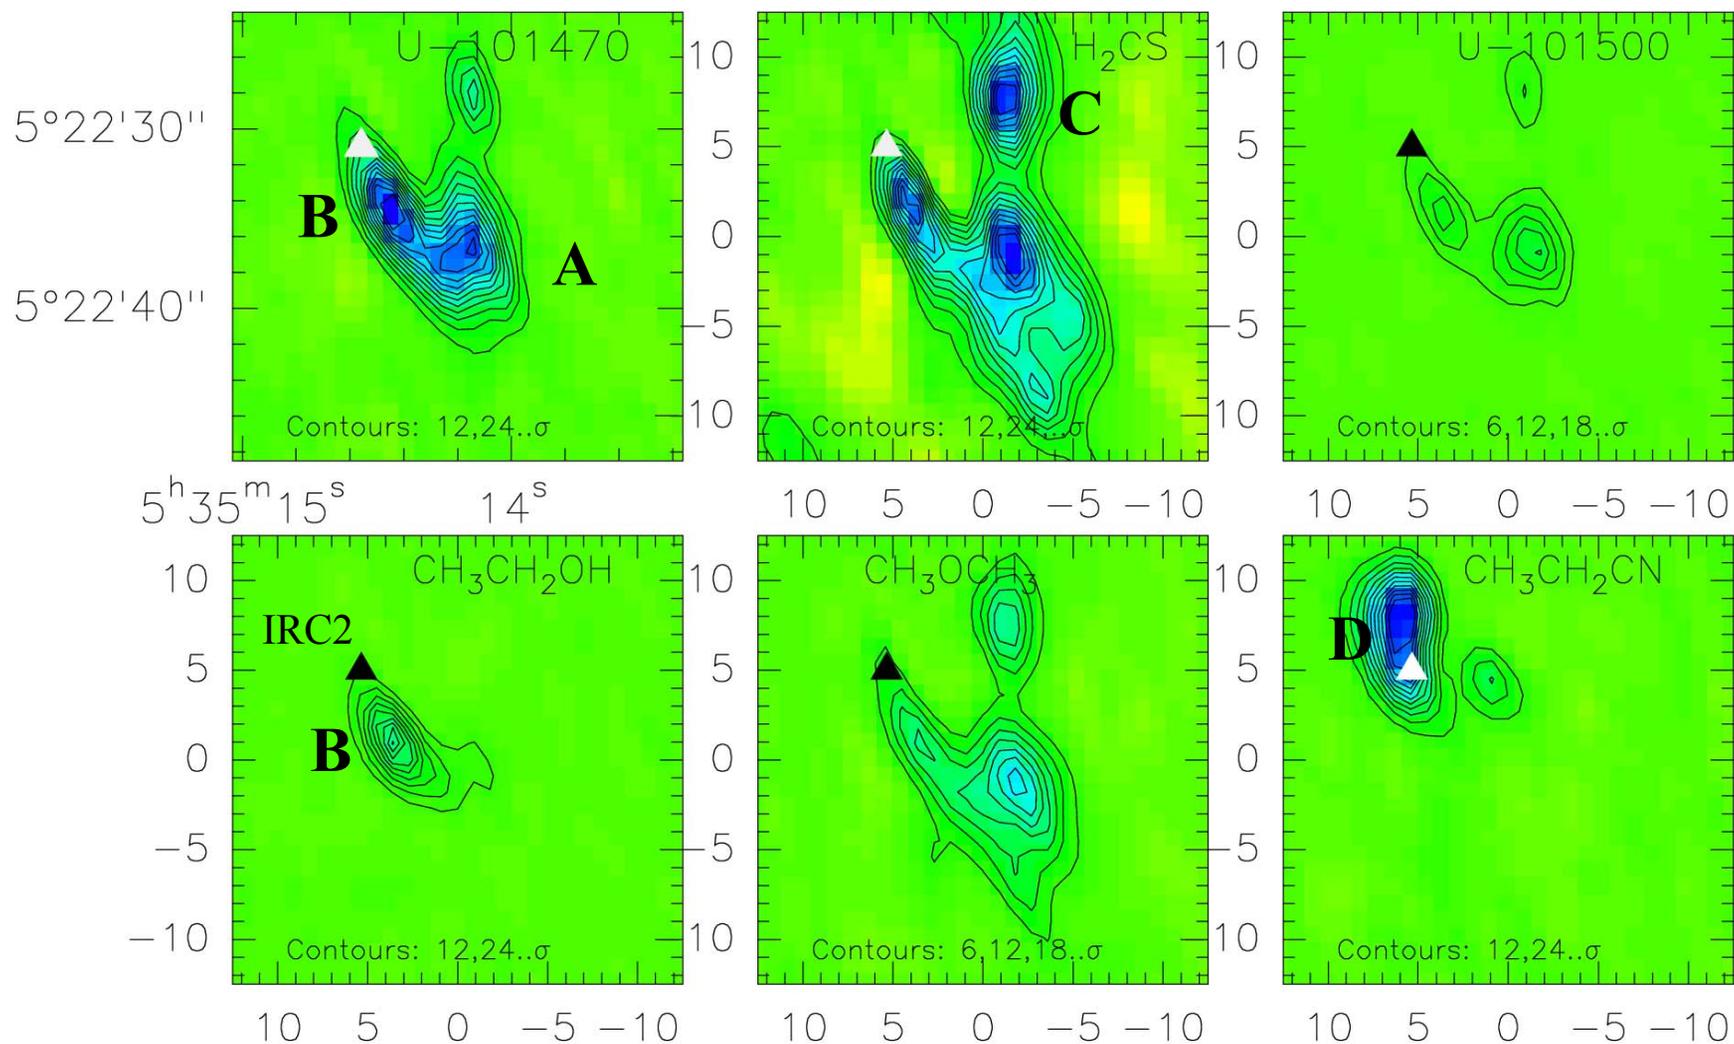

# Interstellar Molecules: where?

- Diffuse IS clouds
- **Cold dark clouds**
- Protostellar cores
- **Hot cores (star forming regions)**
- **Circumstellar disks**
- **Circumstellar envelopes**
- **Jets and shocked regions**
- **External galaxies: up to  $z=6.4$ !**

## Orion-IRC2 and Hot Core

**Maps of Orion-IRC2 in the lines of 6 different molecules:  
The molecules arise from different hot cores (or corinos) labelled A,B,C  
and D.**

**Guelin et al. (2006)**

# AGB star envelope IRC+10216

Spectral line survey 80-250 GHz  
Cernicharo, Guelin, Kahane (2000)

## IR emission

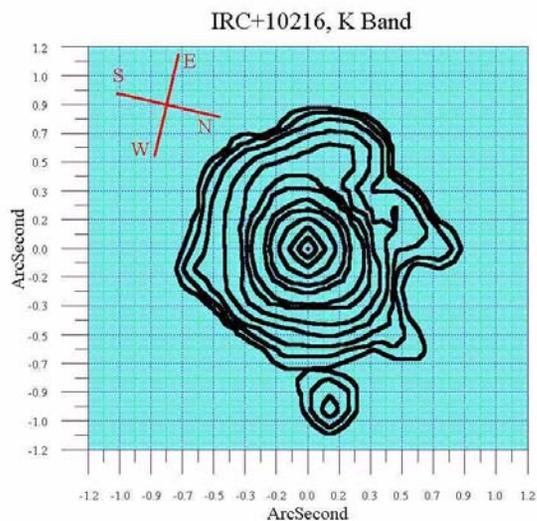

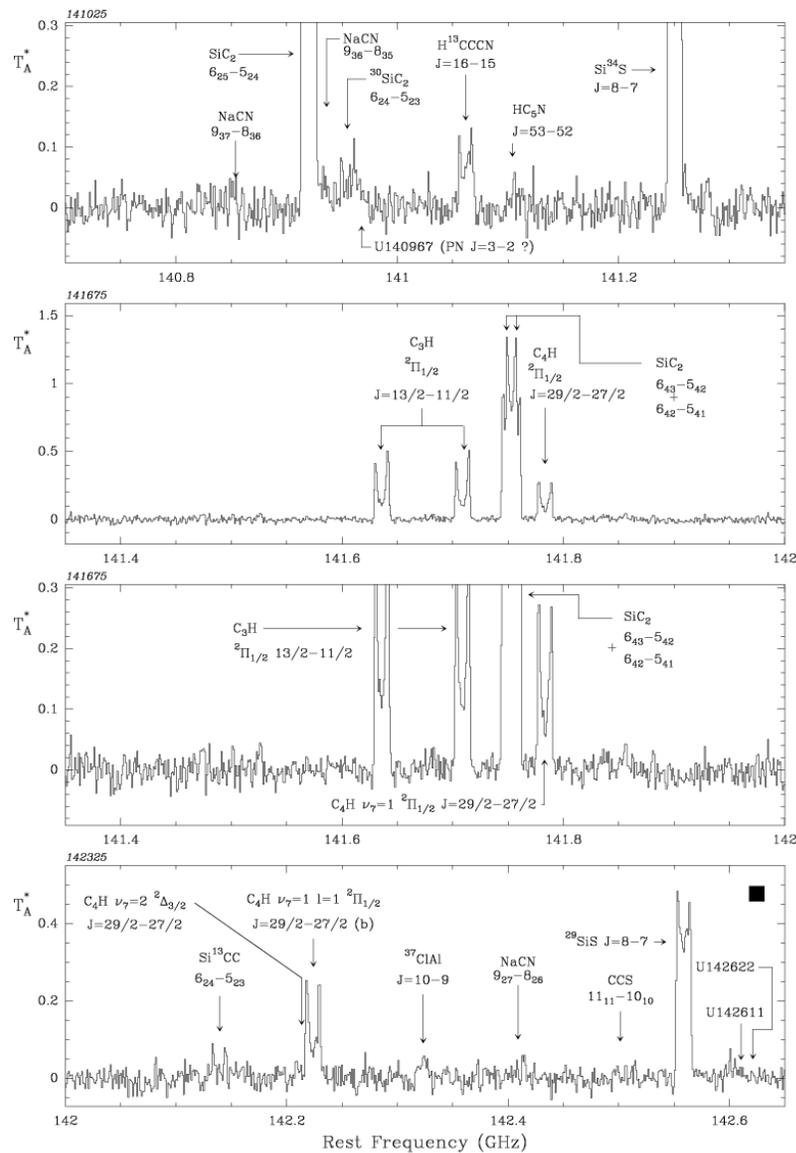

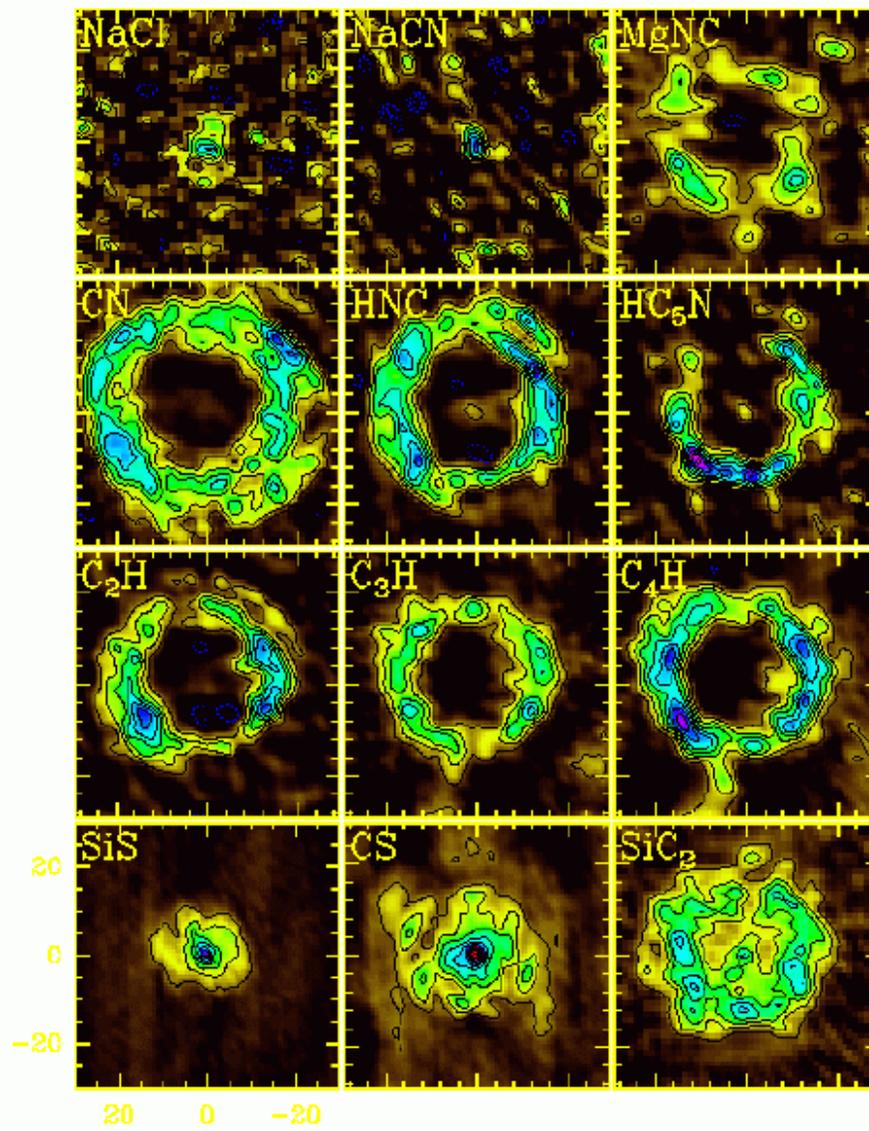

Figure 3: Contour plot of the carbon rich star IRC+10216.

## M82: a different kind of chemistry

CH<sub>3</sub>OH and HNCO undetected in these maps

CN, C<sub>2</sub>H and HNC bright & more extended than CO → *effect of strong radiation field*

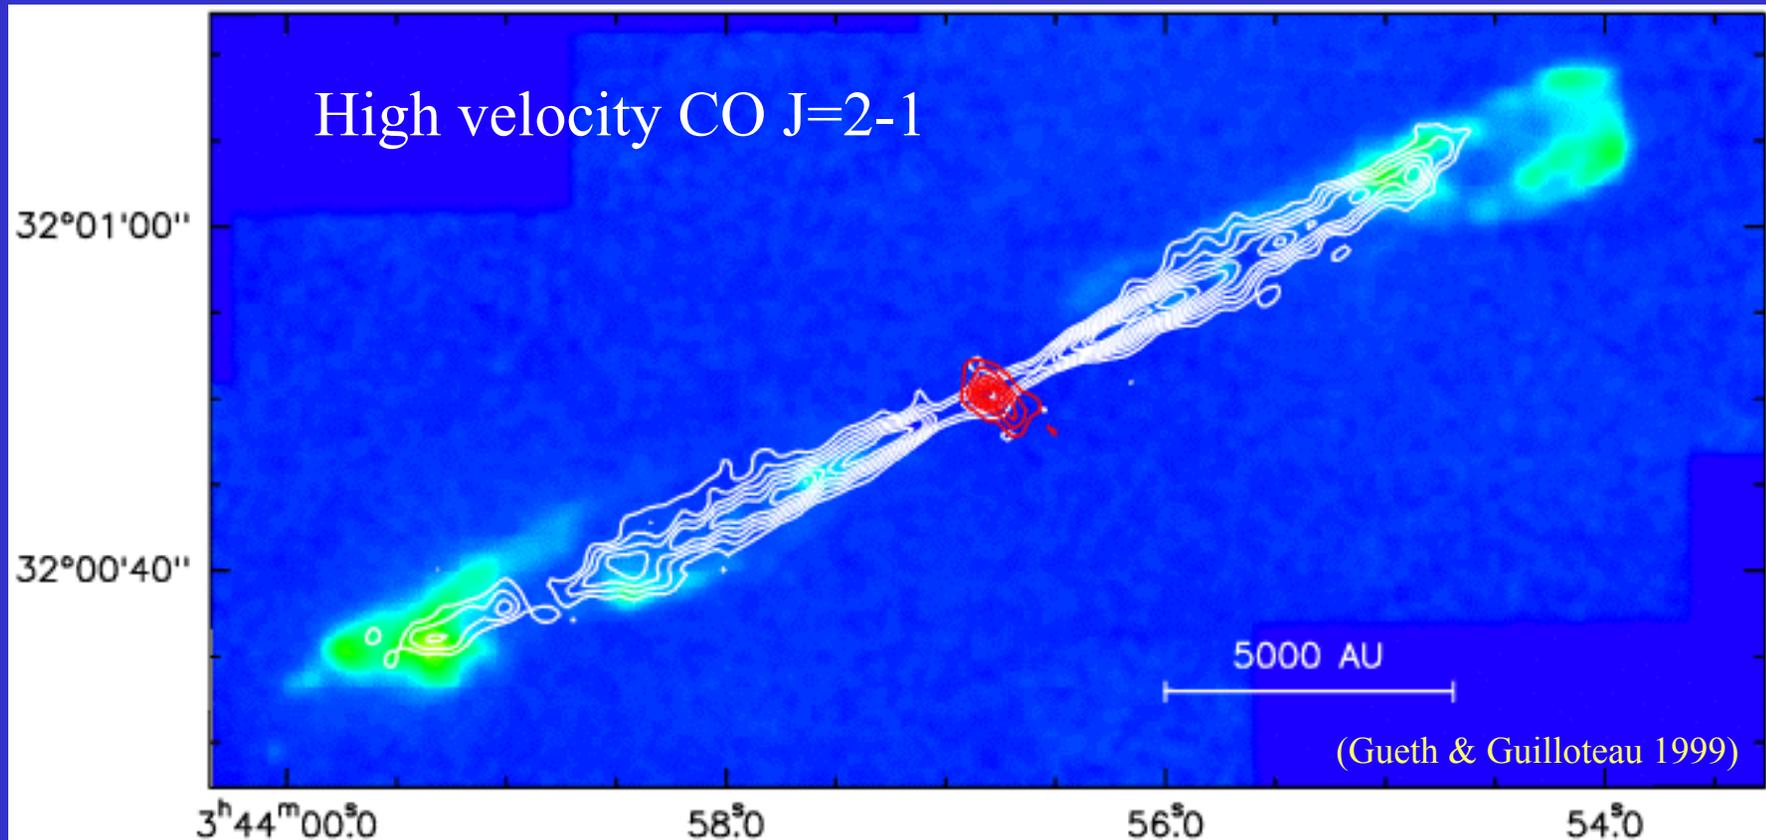

BIMA observations (Meier & Turner, in prep)

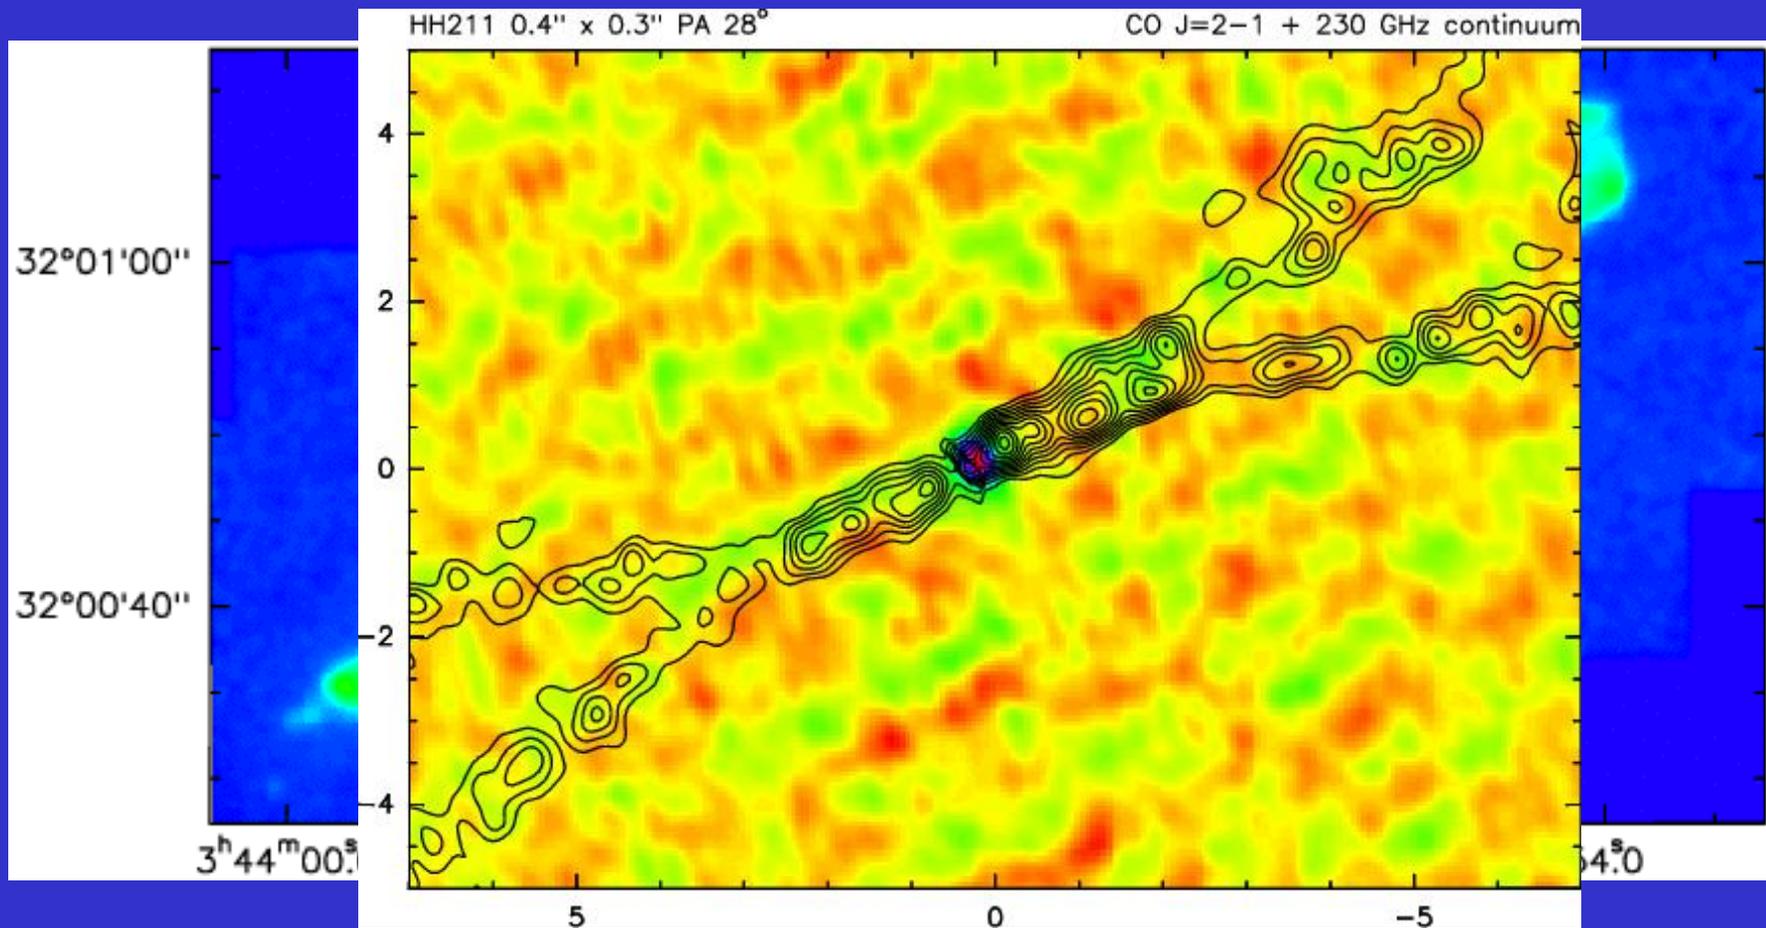

**M82 "giant PDR":** Garcia-Burillo et al. 2002 (HCO)  
Mauersberger & Henkel 1991, Henkel et al. 1991

# HH211 at 1.5'' resolution

Molecular outflow driven by a **Class 0 low-mass protostar**  
(dynamical age  $\sim 1000$  yr, distance of 300 pc)

# 1.5'' $\rightarrow$ 0.3'' resolution

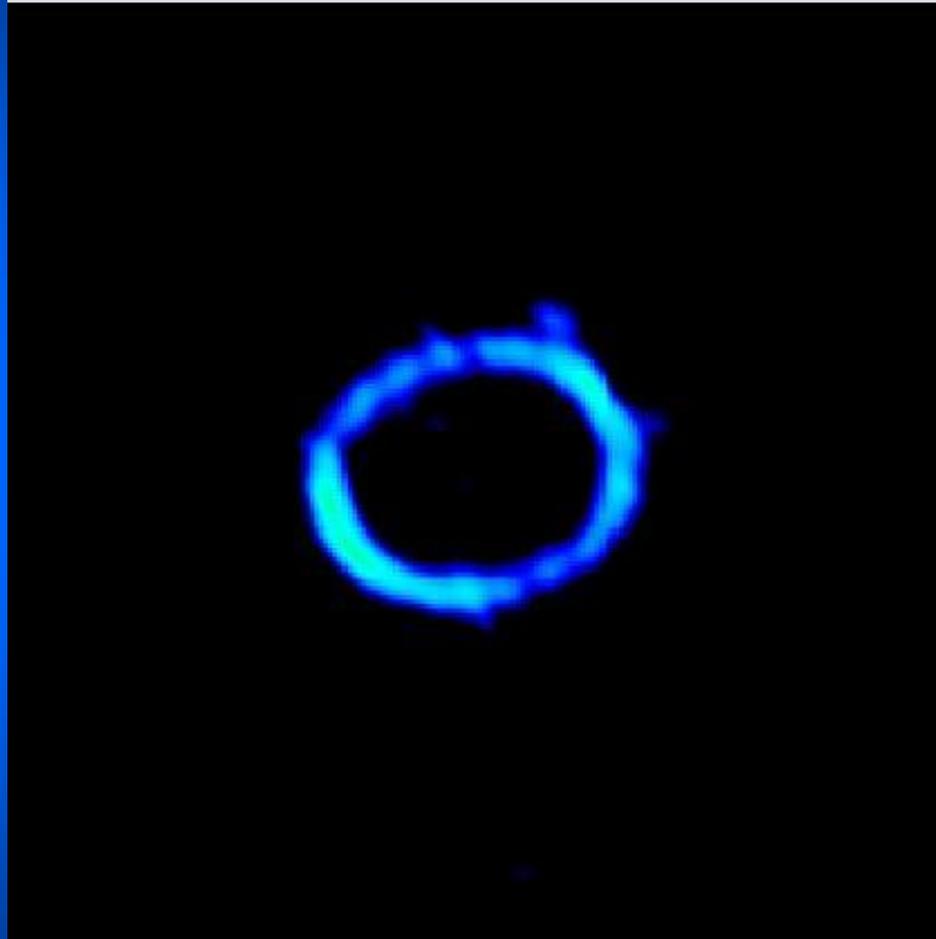

Oct. 6-10, 2008

6<sup>th</sup> IRAM Interferometry School 2008

Gueth et al. (2008)

# GGTau in the continuum at 267 GHz

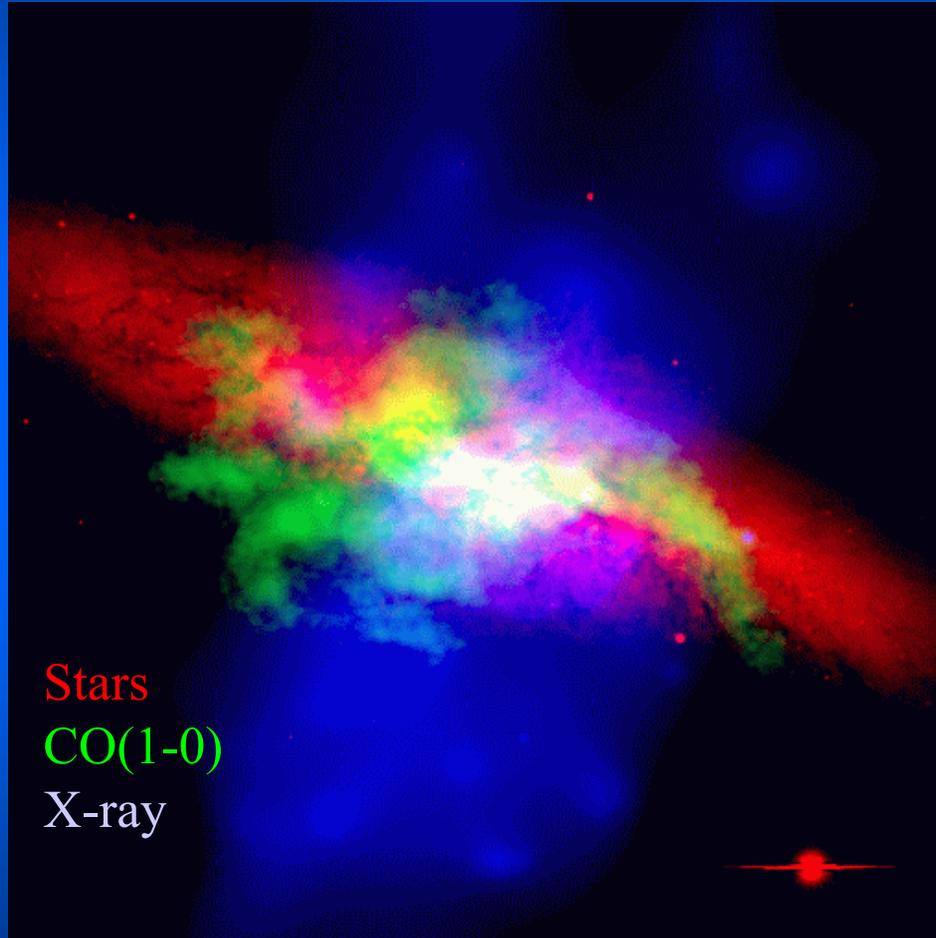

Beam  $0.45'' \times 0.25''$

*Pietu et al. 2008*

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

# Example of a starburst: M82

Prominent starburst at 3.9 Mpc  
(1' ~ 1.1 kpc)

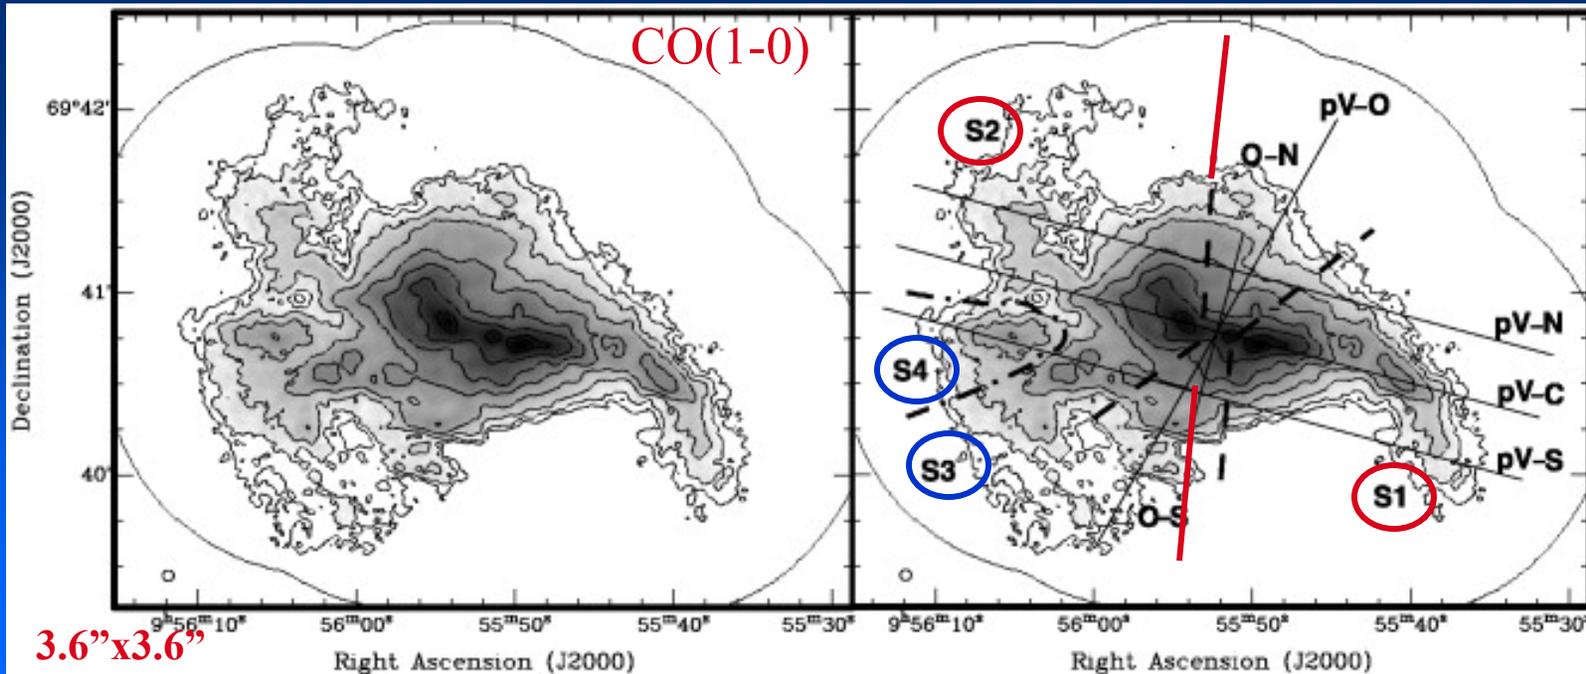

Central regions are site of tremendous star-forming activity: H $\alpha$ , FIR, X-rays outflows, SNRs

$M_{\text{tot}} \sim 2.3 \times 10^8 M_{\text{sun}}$  in center, dense and warm gas

In interaction with M81:

M81-M82 tidal tail – (Yun et al. 1993)

→ Triggered star formation

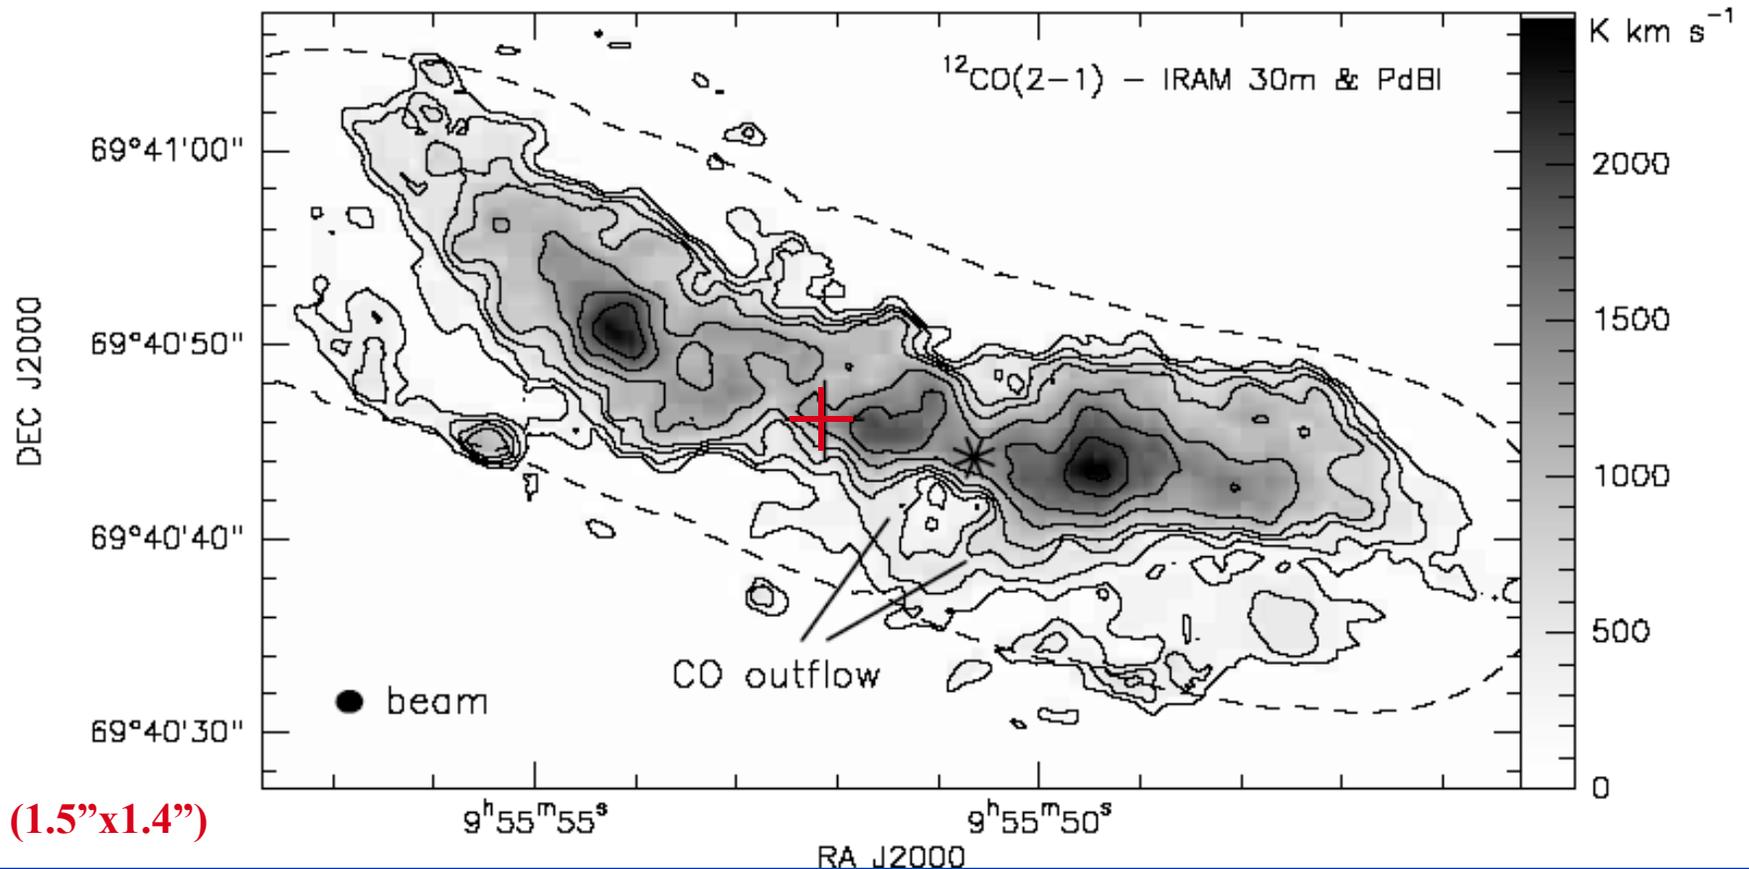

(~70 pc)

Labels of the molecular streamers (S1–S4) and the outflow gas (O-N and O-S);

- Detection of molecular streamers – S1 (and S2) similar orientation and velocities as the HI streamer that point toward M81
- The molecular gas in the inner region is severely affected by the interaction with M81 and its redistribution is the likely trigger of the starburst activity
- The distribution is extended, almost in a halo comparable to ionized gas
  - ➔ From velocities, the gas is out flowing through cone into the halo
  - ➔ Enrichment of the IGM

# M82

## CO (2-1) PdB+ 30-m

The dynamical center of the molecular gas coincides with the 2.2 microns nucleus

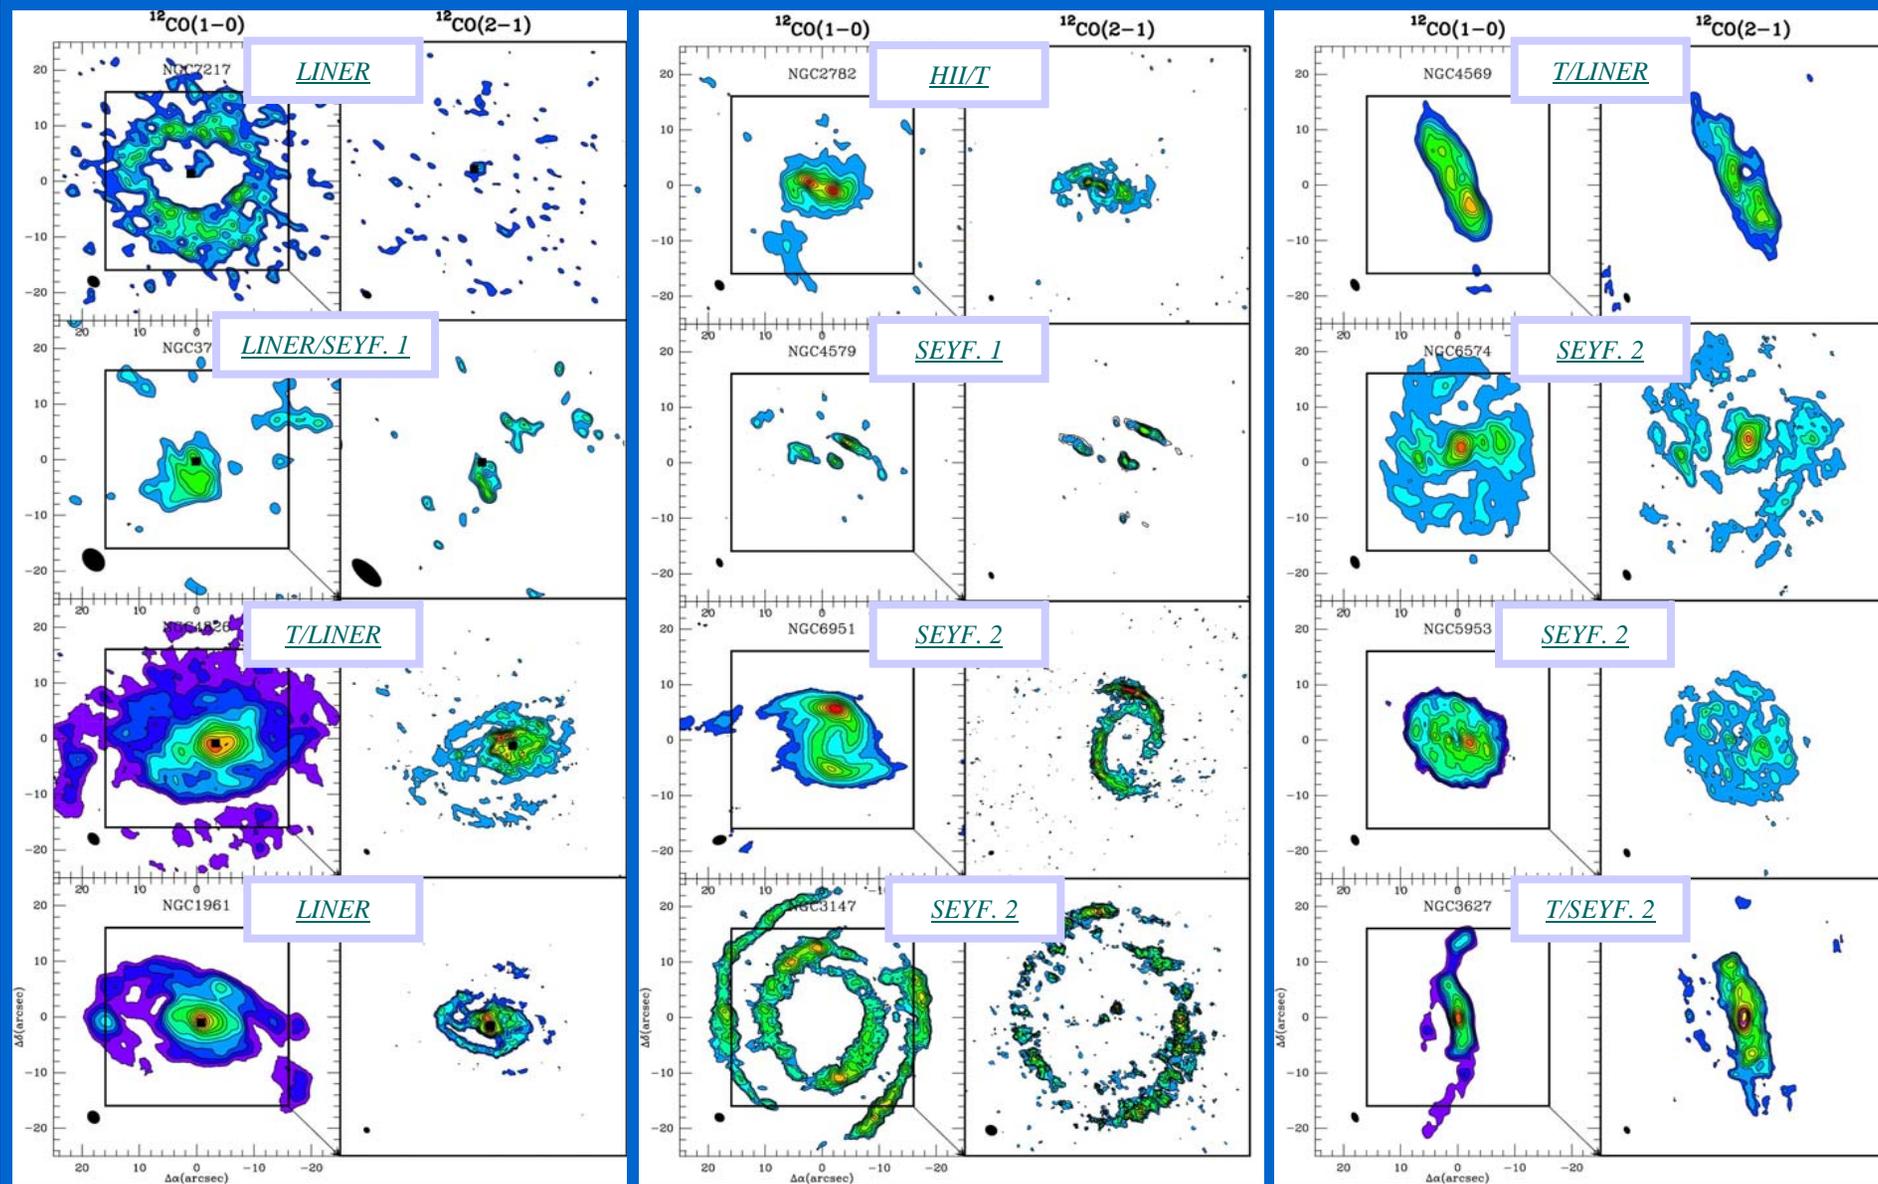

*Weiss et al. (2001)*

# Nuclear Gas Dynamics

## The NuGa View

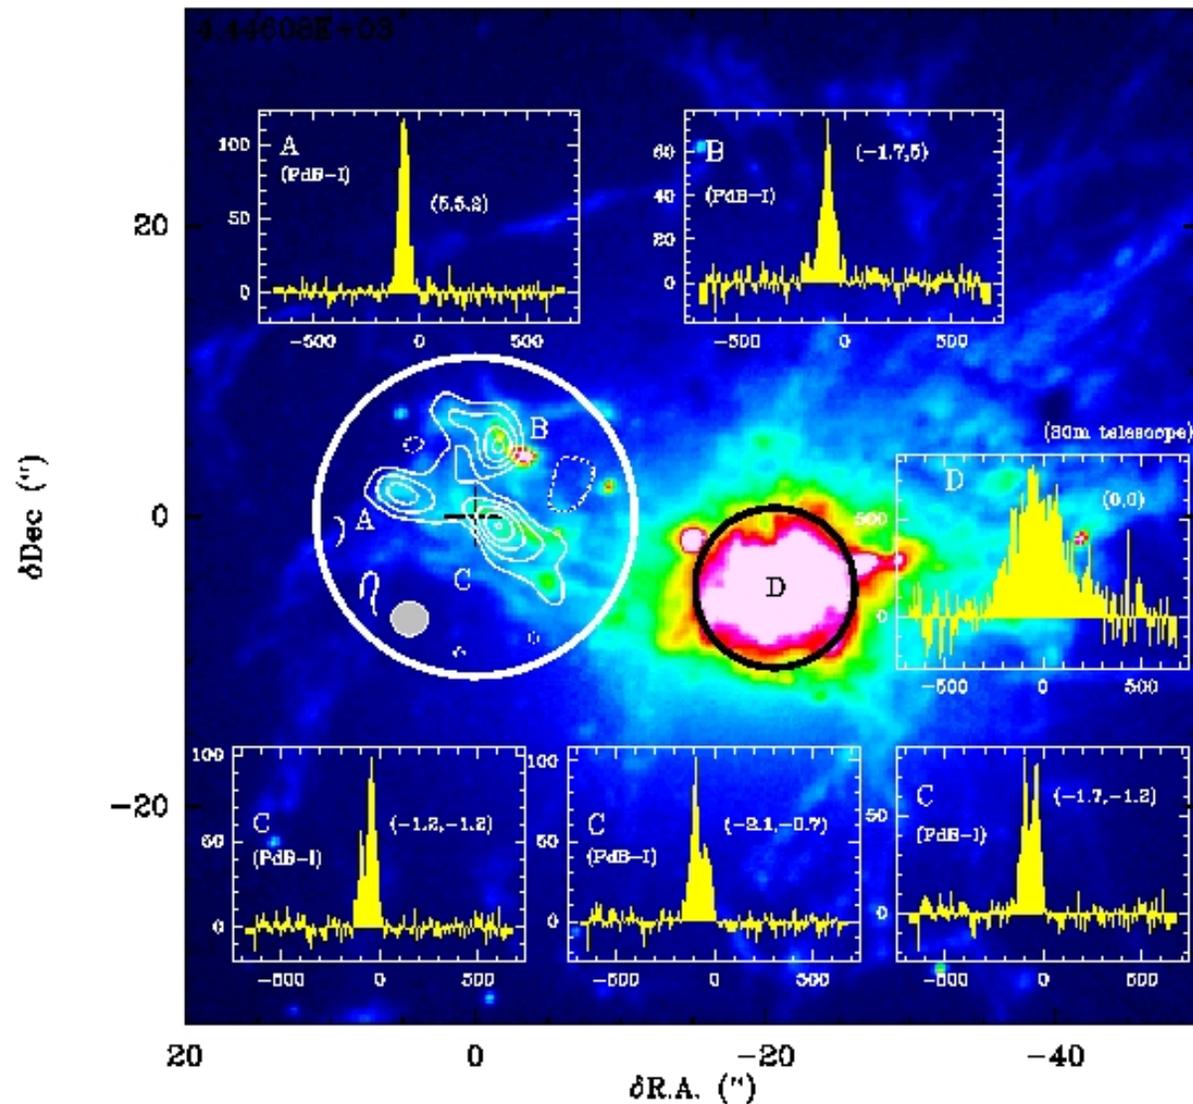

## Detection of CO(2-1) emission in the H $\alpha$ filaments surrounding the galaxy NGC1275

→ Cold molecular clouds that may fall back in the gravitational potential well of the galaxy

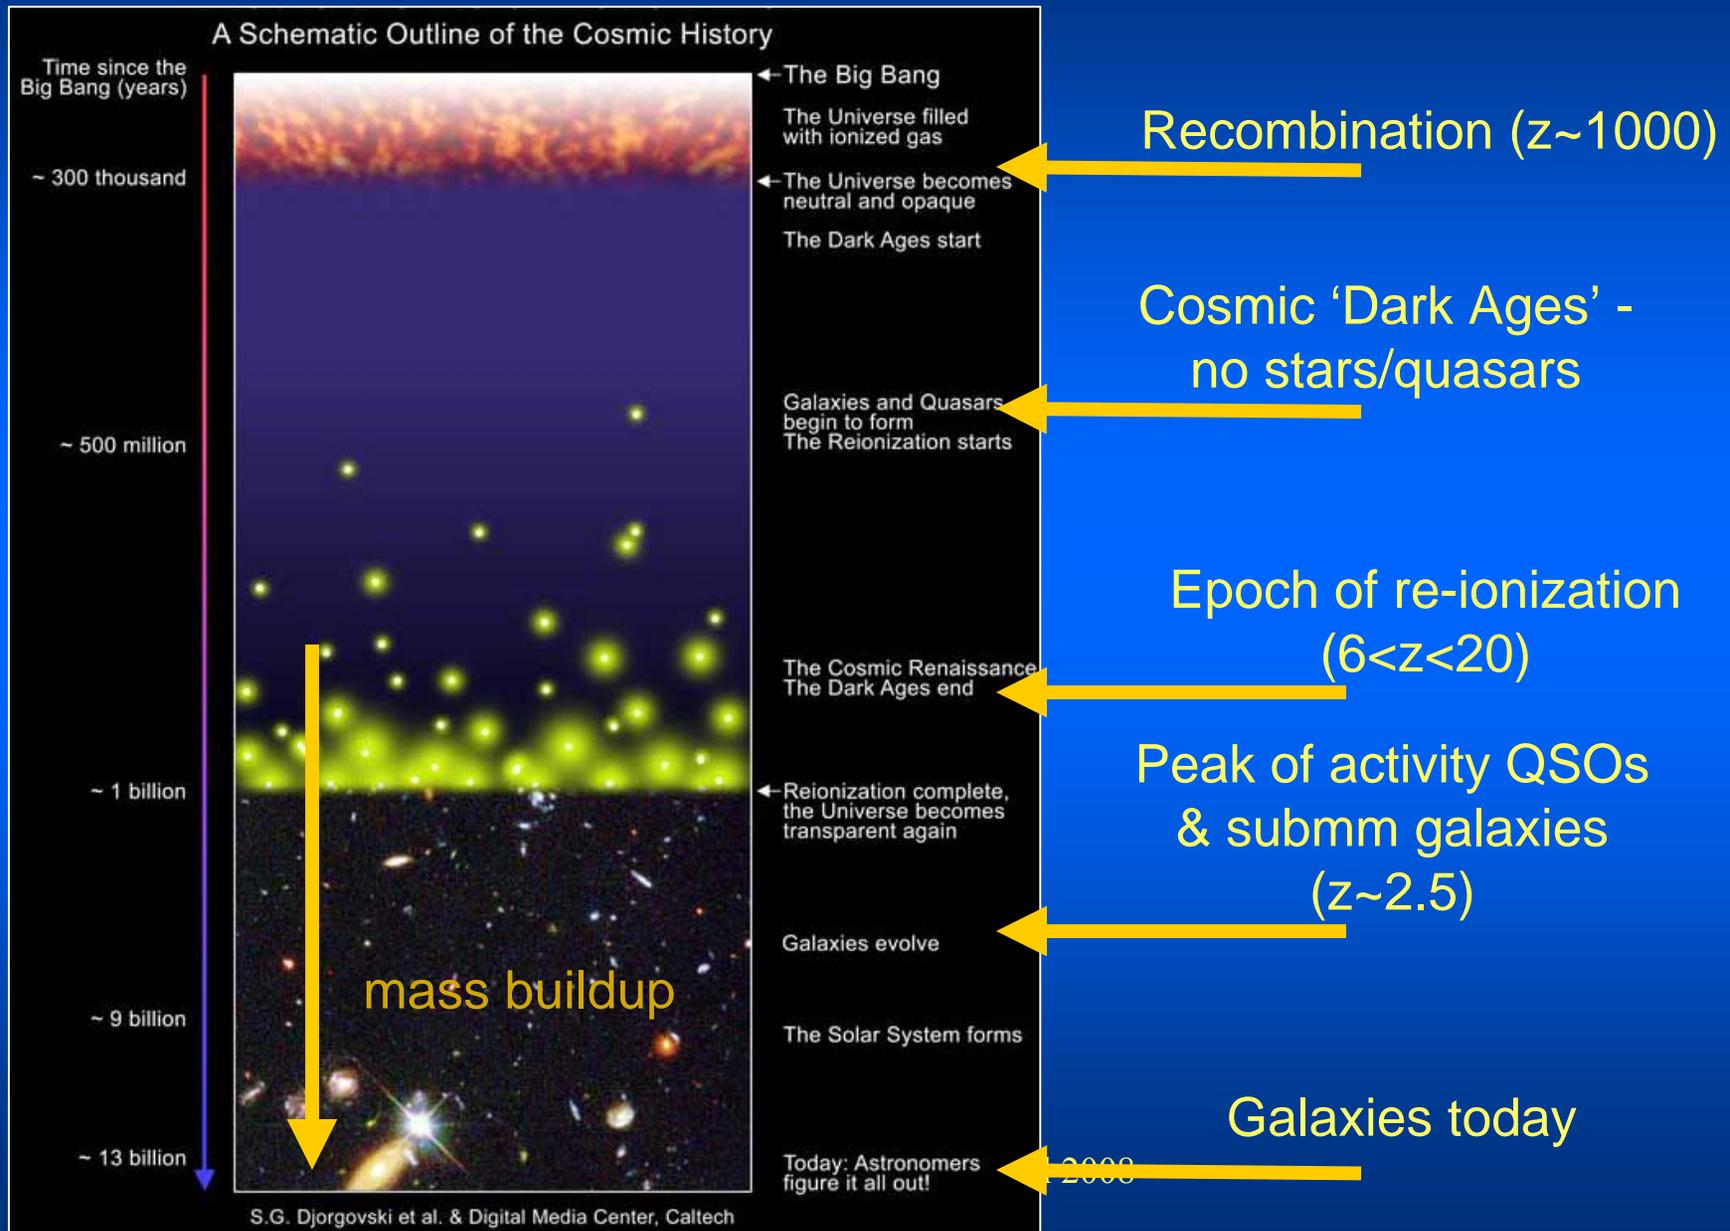

→ Positive feedback scenario

→ Recent detection of CO as far as 50 kpc from the galactic center

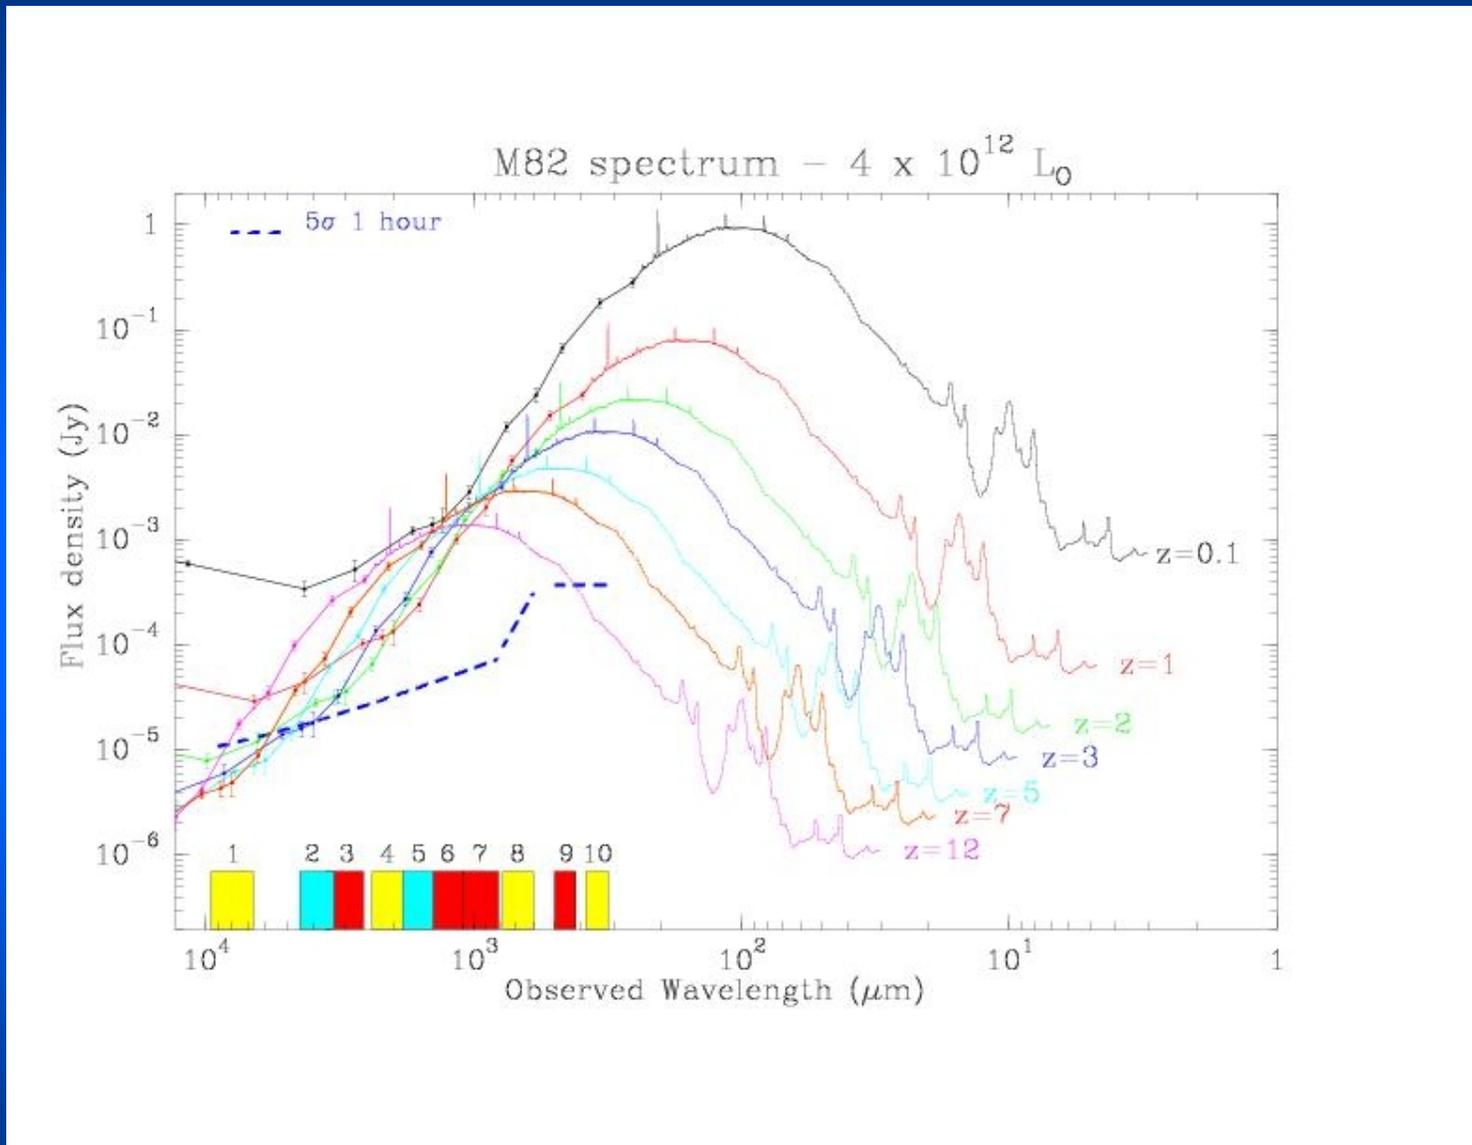

*Salome et al. 2008*

# History of the Universe

# Inverse K-correction

Oct. 6-10. 2008

6<sup>th</sup> IRAM Interferometry School 2008

# The Galaxy Cluster A 1835

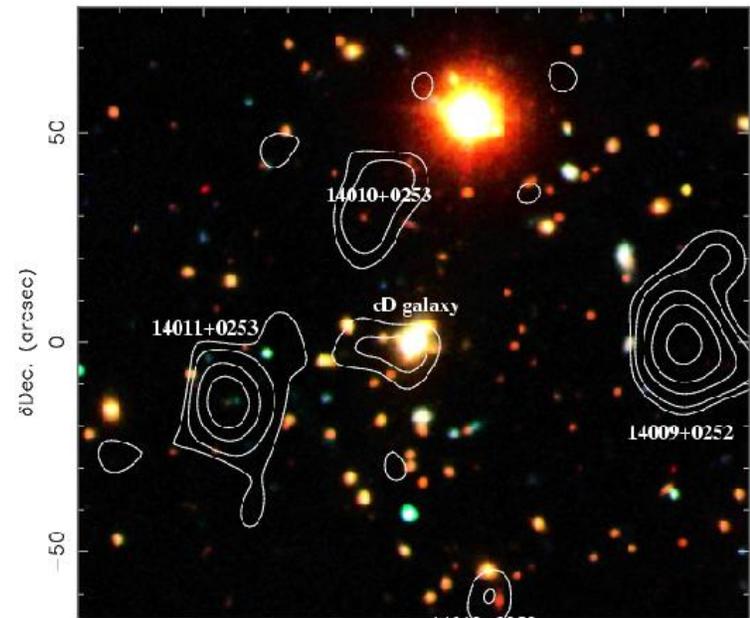

SCUBA image at 850 microns  
superimposed on an optical image.

Complementary information on the  
cluster:

*The submm sources are weak in the  
optical and vice versa.*

- ~300 Deep submm field  
sources known
- Difficult redshift determinations

## Amplification

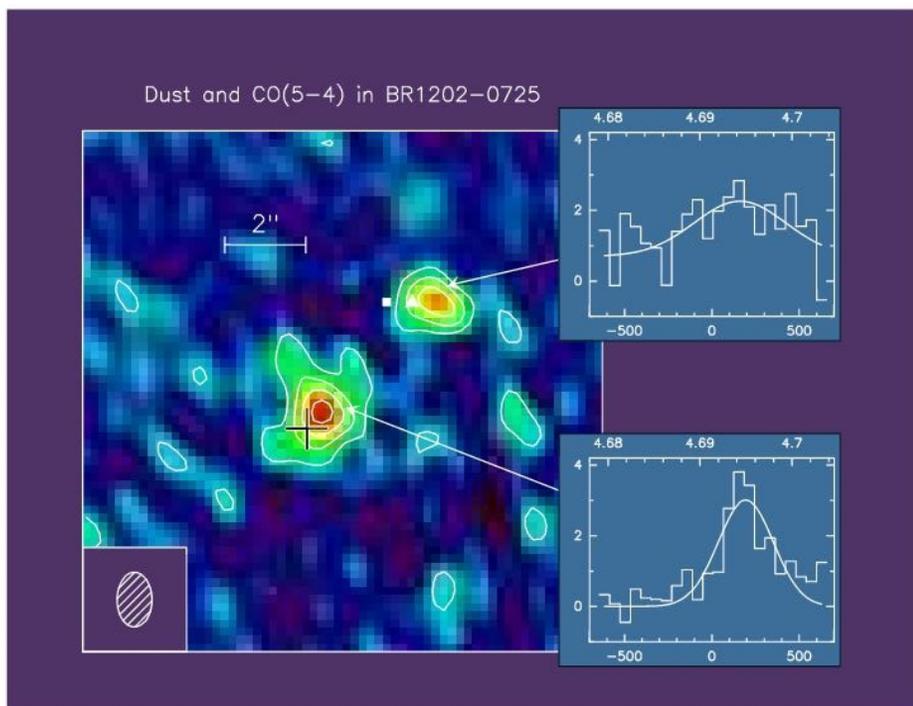

**Iverson et al. (2000)**

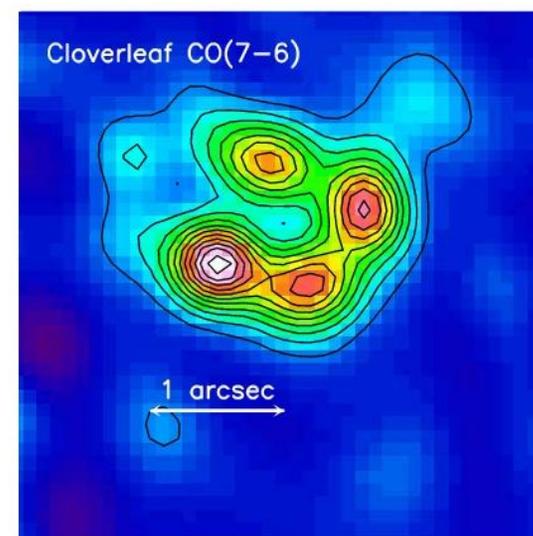

# The two next detections of CO at high redshift

**BR1202-0725 at  $z=4.69$**

*Omont et al. (1996)*

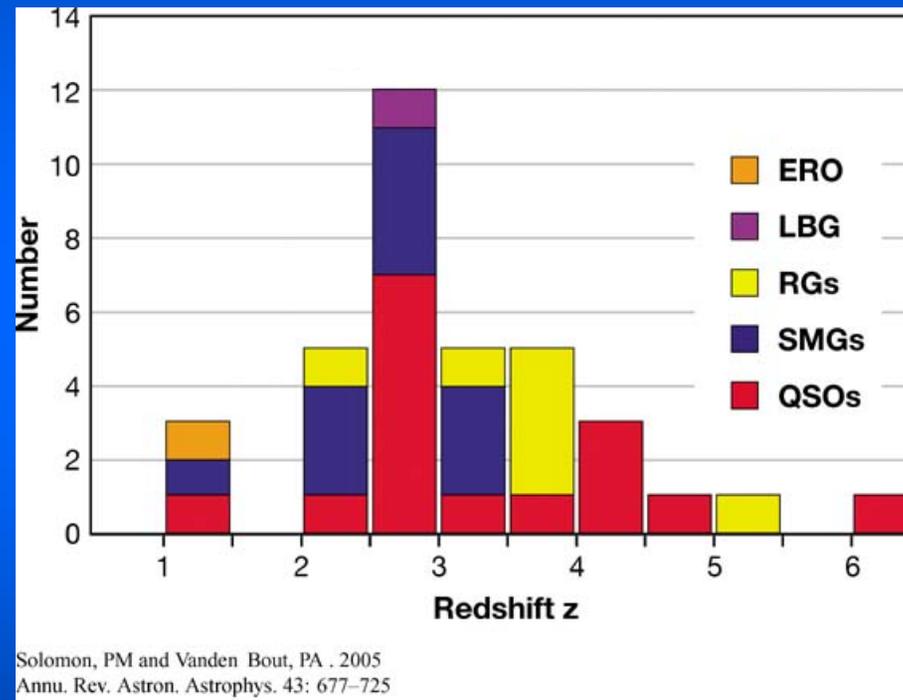

**Cloverleaf at  $z=2.6$**

*Alloin et al. (1997)*

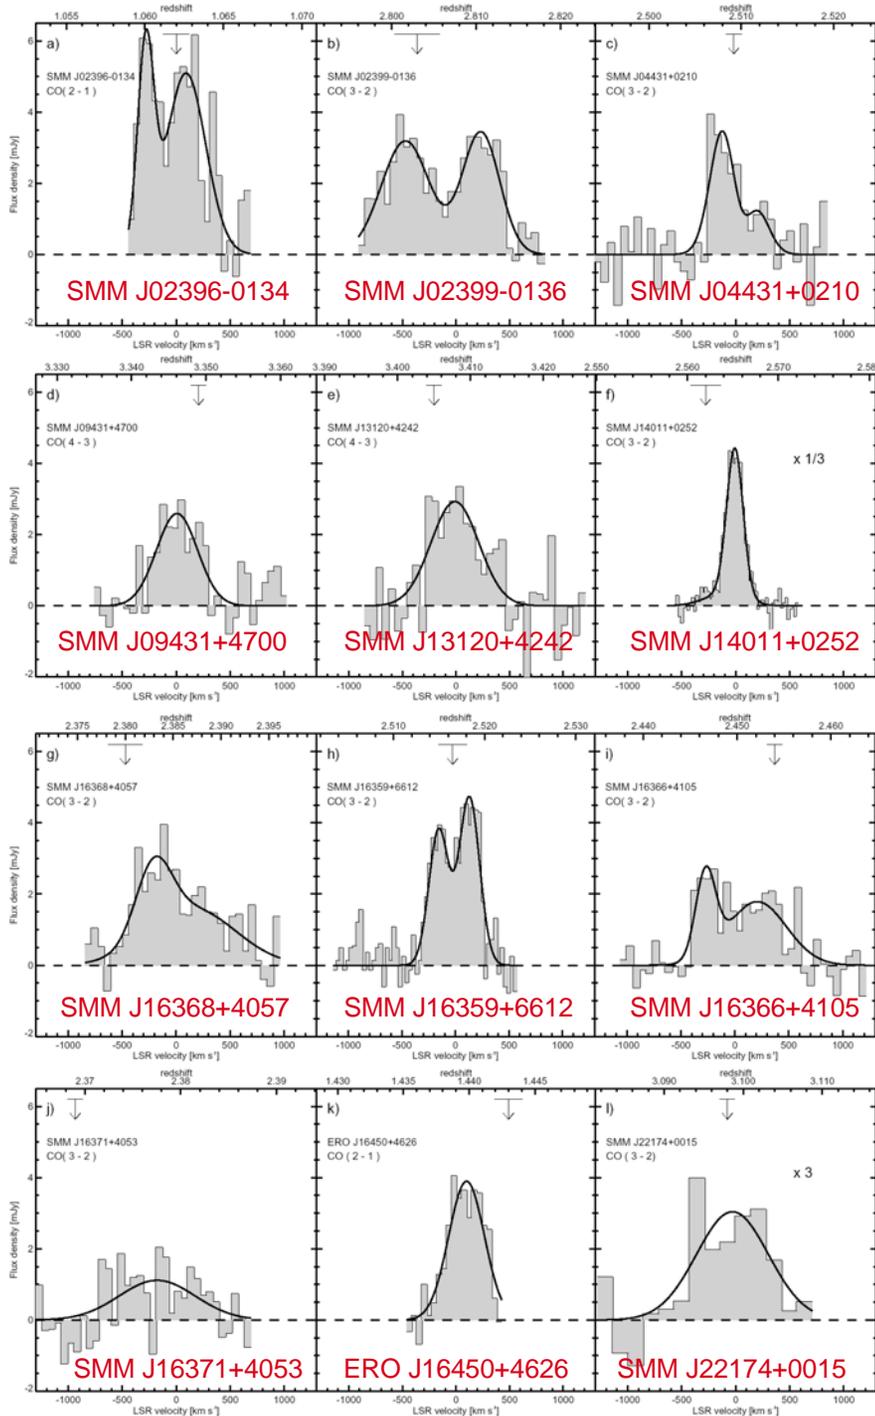

## Distribution in redshift of high-z sources

Despite the large selection effects of the flux-limited sample, the distribution reflects the current understanding of the star formation history in the Universe

# CO Survey of sub/mm Galaxies (SMG)

- 18 radio-detected submm galaxies with known optical/near-IR redshift detected in CO (sep. 2007)
- $1 < z < 3.5$
- Variety of profiles:  $780 \pm 230$  km/s
- Mergers/Rotating Disks
- Star Formation Rate:  $720 M_{\text{sun}}/\text{yr}$
- $M_{\text{H}_2} \sim 3 \times 10^{10} M_{\text{sun}}$
- $M_{\text{dyn}} \sim 10^{11} M_{\text{sun}}$
- *The submm-population consists of gas rich and massive, composite starbursts/AGN systems, which are going a major burst of star formation (i.e.  $10^8$  yr) and evolving in  $m^*$ -galaxies*

# Resolving $z > 4$ CO Emission

## Paving the Road for ALMA

Ultimate goal: resolve CO emission spatially/kinematically

⇒ Dynamical masses, host galaxy sizes, disk galaxies vs. mergers

⇒ compare to optical/NIR: evolution (?) of  $M_{\text{BH}}-\sigma$  relation

**critical scale: 1 kpc = 0.15" @  $z=4-6$**

$M_{\text{BH}}$	black hole
$M_{\text{bulge}}$	stars
$M_{\text{gas}}$	gas
$M_{\text{dyn}}$	<b>dynamical mass</b>

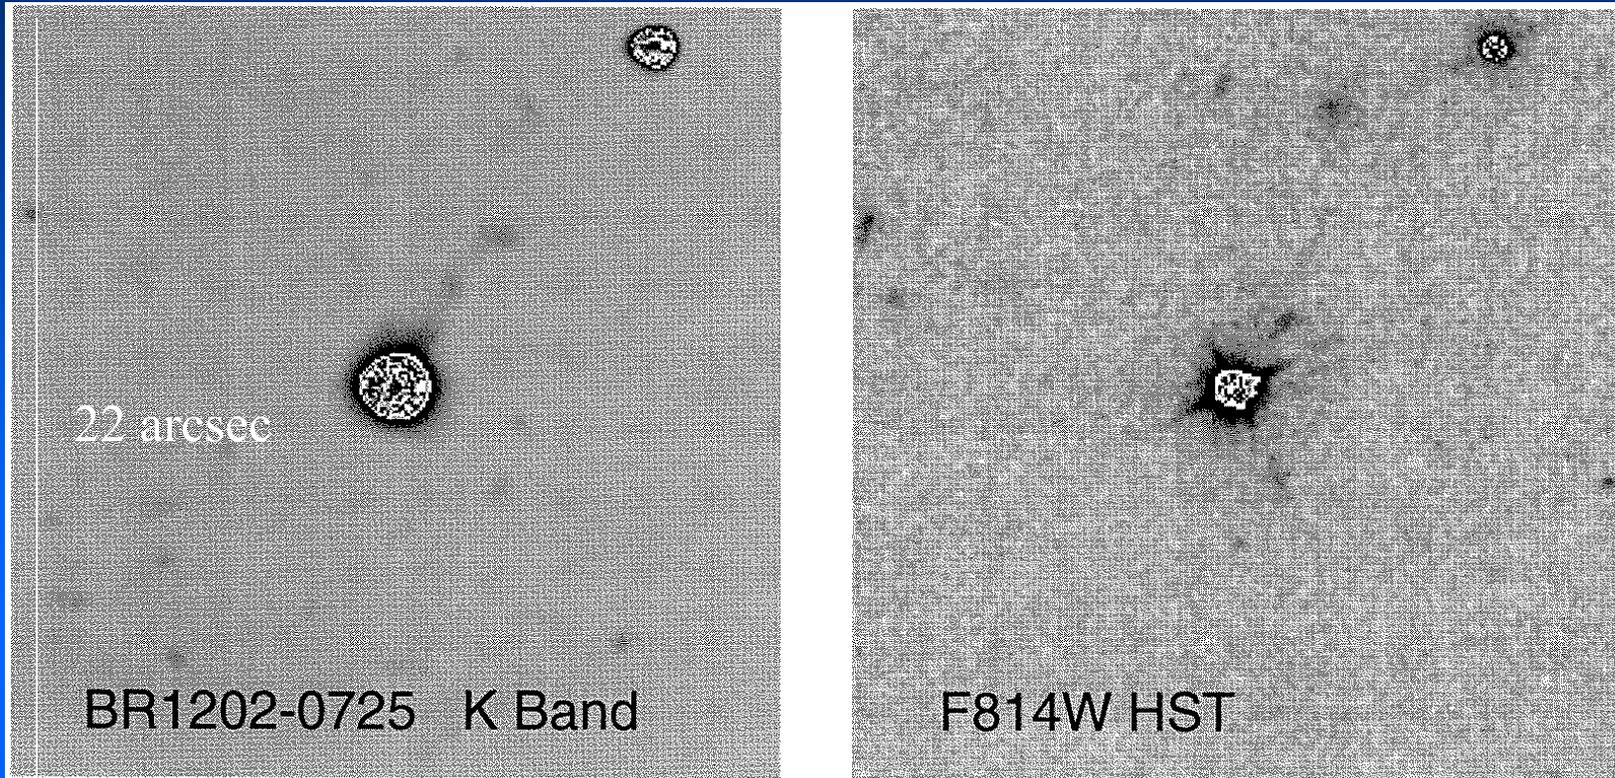

*Only VLA / IRAM can observe CO in  $z > 4$  QSOs at 0.15"-0.3"/1-2 kpc resolution (B array, 10 km; A array, 800 m)*

*⇒ We don't need ALMA for (all of) this!*

*Caveat: needs 50-80 hours per source (VLA) – only one/two track at PdBI*

*& the best weather conditions*

## BR1202-0725 at $z=4.69$

Comparison of K-band image (left panel) of the region near the quasar BR 1202–0725 with the HST F814W (“wide I,” right panel) image, showing the extension in continuum light to the northwest in both images.

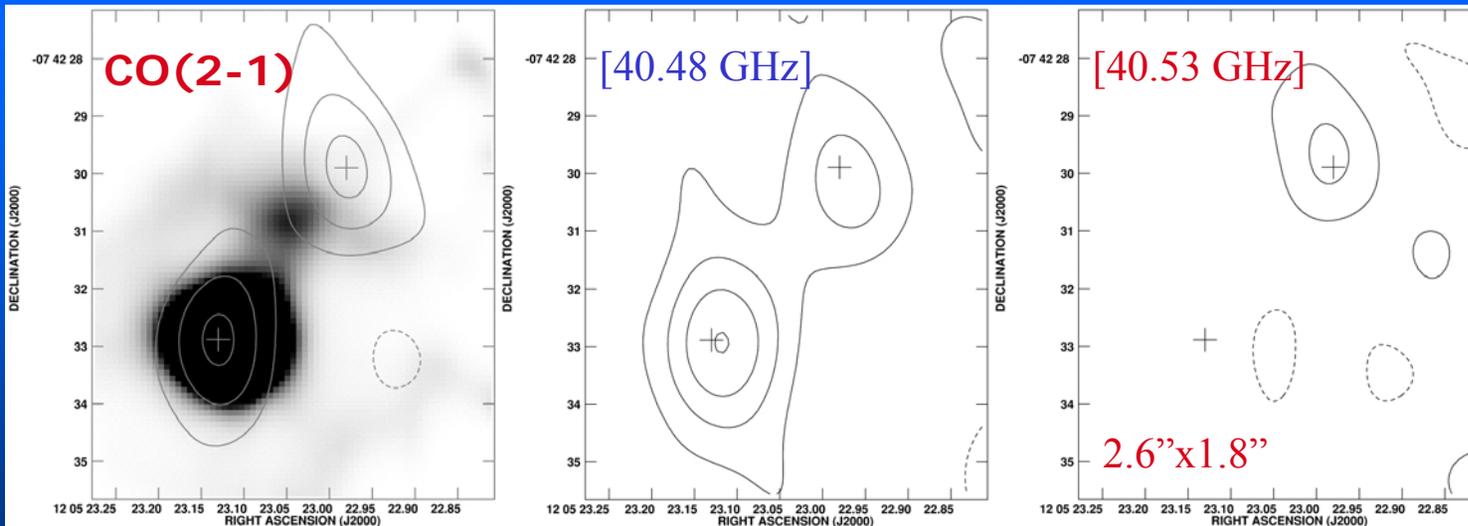

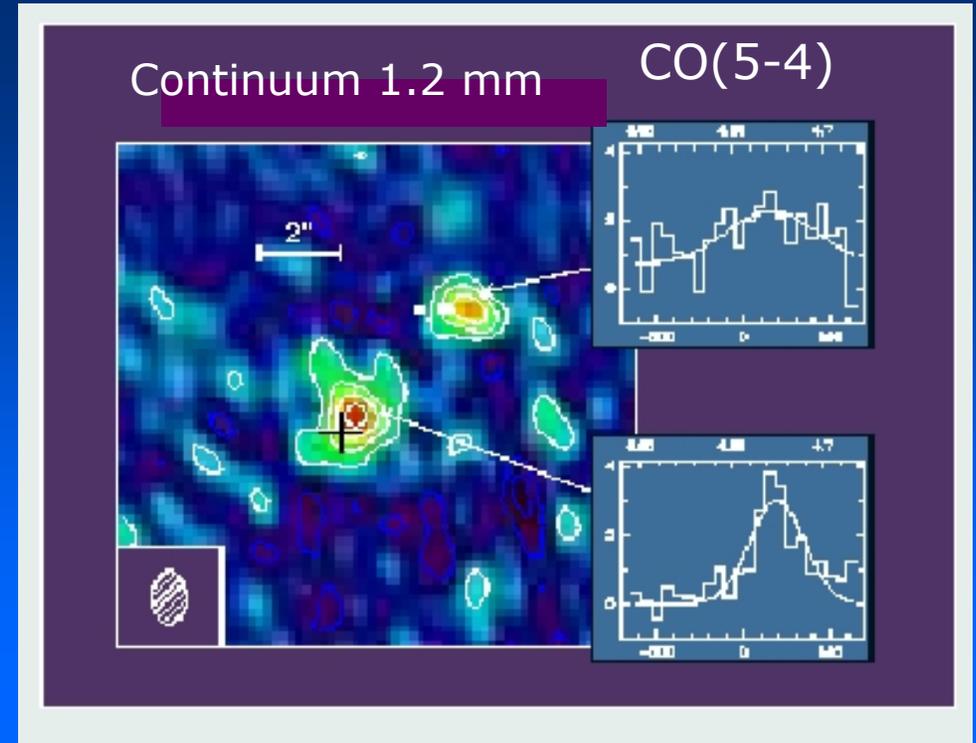

Evidence for star-forming activity from  $\text{Ly}_{\alpha}$  line emission ( $\sim 1100$  km/s)

Super-wind activity expelling material in the halo region

*Hu et al. 1996*

Two sources in CO & dust emission  
 Southern source - 65% of total

6<sup>th</sup> IRAM Interferometry School 2008

## Other lines: Atomic Carbon (CI)

CI lines detected in Cloverleaf, F10214, SMM14011, PSS2322

- typically fainter than CO by a factor of few *[e.g., Weiss 2003, 2004, Pety 2004]*

1GHz BW @ 2mm

→ Important for follow-up, but not line of choice for search

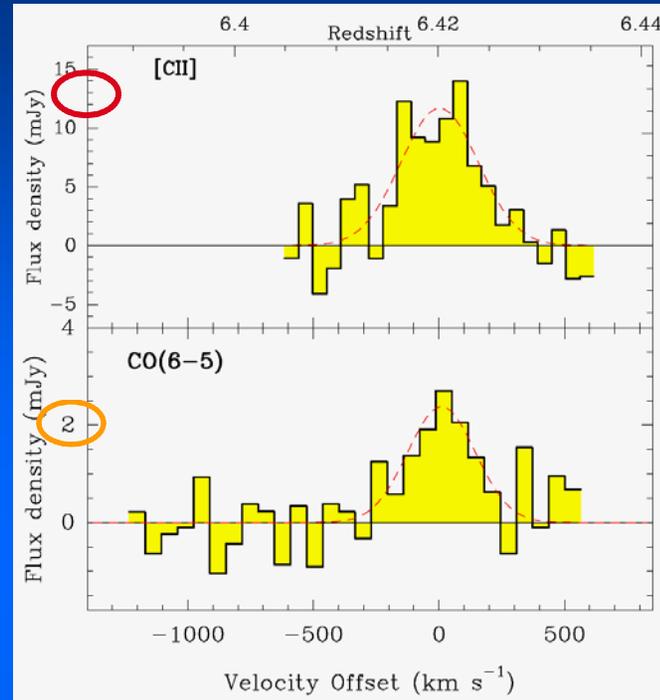

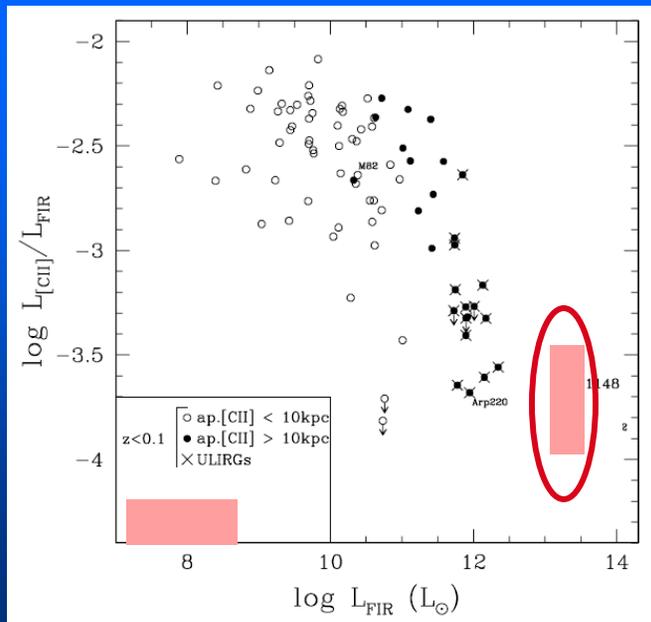

# [CII] detected at z=6.4

J1148+5251 (z=6.42)  
 Maiolino, Cox et al. 2005

$$L_{[\text{CII}]} = 4.4 \times 10^9 L_{\text{sun}}$$

$$L_{\text{FIR}} = 2 \times 10^{13} L_{\text{sun}}$$

$$L_{[\text{CII}]} / L_{\text{FIR}} = 2 \times 10^{-4}$$

30-meter  
 36 hours integr.

Note: six times brighter  
 than brightest CO line!

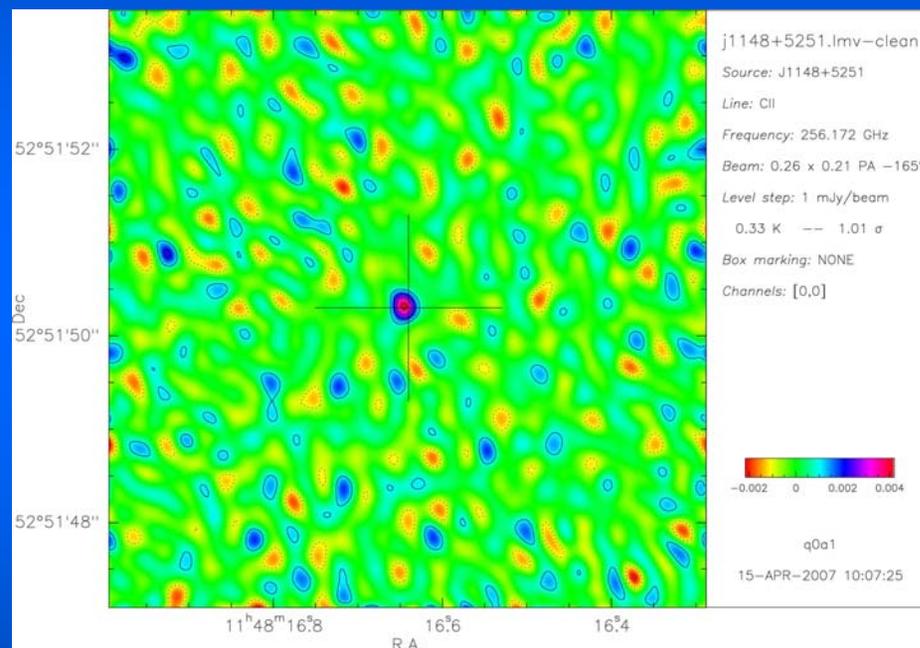

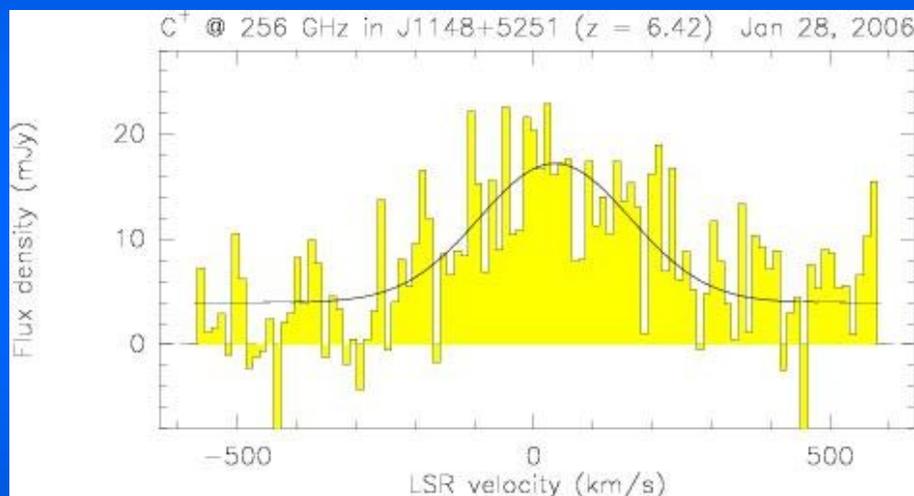

Though 'worst case' still detectable in [CII]

Follow-up to resolve line: PdBI (0.3")

[CII] also detected in B1202 [Iono et al. 06]

Earlier limits on high-z sources: Bolatto et al. 04,  
 Marsden et al. 05, van der Werf 98, ...

# $C^+$ at 256.17 GHz in J1148+5251 at $z = 6.42$ using the Plateau de Bure interferometer
